

# Total Deposition 2015

National Atmospheric Deposition Program

### 2015 Total Deposition

**On the cover:** Comparison of the 3-year averages of total nitrogen deposition for the periods 2000-2002 and 2013-2015. Significant reductions in nitrogen deposition have occurred over the past decade due to implementation of emission control programs for both the power and transportation sectors.

#### **Suggested Acknowledgement and Citation:**

Data users that present and/or publish research based on total deposition values derived from this multi-organization effort should acknowledge the Total Deposition (TDEP) Science Committee and the National Atmospheric Deposition Program (NADP). A suggested acknowledgement is:

“We acknowledge the Total Deposition (TDEP) Science Committee of the National Atmospheric Deposition Program (NADP) for their role in making the TDEP data and maps available.”

To cite data or maps from this summary, please use the following citation:

Percentage of total chloride deposition as dry deposition in 2015 .....	19

## About the Total Deposition Maps

In October 2011, the National Atmospheric Deposition Program (NADP) Executive Committee formed the Total Deposition (TDEP) Science Committee. The mission of TDEP is to improve estimates of atmospheric deposition by advancing the science of measuring and modeling atmospheric wet, dry, and total deposition of species such as sulfur, nitrogen, and mercury by providing a forum for the exchange of information on current and emerging issues within a broad multi-organization context including atmospheric scientists, ecosystem scientists, resource managers, and policy makers.

For more information regarding TDEP, please visit the NADP-TDEP web page at

<http://nadp.isws.illinois.edu/committees/tdep>.

## What is Total Deposition?

Total deposition estimates are derived from summing wet and dry deposition. Members of this multi-organization committee worked to develop a “hybrid approach” to mapping total deposition that combines measured and modeled values. One of the initial goals of TDEP was to provide estimates of total sulfur and nitrogen deposition across the U.S. for use in critical loads and other assessments, where loading results in the acidification and eutrophication of ecosystems. Measured values are given more weight at the monitoring locations, and modeled data are used to fill in spatial gaps and provide information on chemical species that are not measured by routine monitoring networks. One of the main advantages of this approach is that it will provide continuous spatial and temporal coverage of total deposition estimates in the U.S. (beginning in 2000), which until this point, have been unavailable.

## Methodology

The original method was published in:

*Schwede, D.B. and G.G. Lear, 2014. A novel hybrid approach for estimating total deposition in the United States, Atmospheric Environment, 92, 207-220. DOI:dx.doi.org/10.1016/j.atmosenv.2014.04.008.*

Updates to the methodology have occurred since the publication of the manuscript and will continue to occur as the science evolves and new information is available. A Revision History and other important information are available at

[ftp://ftp.epa.gov/castnet/tdep/Total\\_Deposition\\_Documentation\\_current.pdf](ftp://ftp.epa.gov/castnet/tdep/Total_Deposition_Documentation_current.pdf) .

In brief, the method for making TDEP maps is as follows:

- Precipitation amounts (p. 8) are obtained by combining measured values of precipitation from NADP networks with precipitation estimates from the Parameter-elevation Regression on Independent Slopes Model (PRISM).

- Wet deposition values are the product of measured values of precipitation chemistry from NADP networks and the precipitation amount calculated above.
- Dry deposition values are obtained by combining measured air concentration data, principally from rural locations with Clean Air Status and Trends Network (CASTNET) sites (<https://www.epa.gov/castnet>), with modeled concentrations and deposition velocities from the Community Multiscale Air Quality (CMAQ) model. In general, modeled air concentrations are adjusted for bias where corresponding measurements are available. Modeled ammonia concentrations have not been adjusted for bias because the relationship between measured and modeled concentrations is not linear.
- Deposition values for unmeasured species (i.e., dry deposition of gaseous PAN, N<sub>2</sub>O<sub>5</sub>, NO, NO<sub>2</sub>, HONO, and organic nitrates) are estimated from the CMAQ model (p. 14).
- Dry deposition values are combined with the wet deposition values to produce the final estimates of total deposition.
- Ammonia deposition is estimated using a bidirectional air-surface exchange model. For terrestrial surfaces, flux pathways include the soil, leaf stomata, and leaf cuticle. Gross ammonia deposition (p. 15) refers to the total amount of ammonia deposited to soil and vegetation within a model grid cell and is the amount used in calculating total nitrogen deposition.
- Net ammonia deposition is calculated by subtracting non-point source emissions, such as those from soils and leaf surfaces, from the gross deposition derived from the bidirectional model. Although point source emissions such as those from confined animal feeding operations and industrial sources are used in calculating air concentrations of ammonia and other air pollutants, they are not included in the net deposition amounts. Positive net deposition values indicate deposition to the landscape, whereas negative values indicate emission.
- S + N equivalent deposition (p. 17) is one measure of the combined acidifying effect of nitrogen and sulfur deposition on ecosystems and is a common metric in critical load determinations. This measure is calculated from the molar equivalents of sulfur and nitrogen deposition and assumes 1 equivalent/mole for nitrogen compounds and 2 equivalents/mole for sulfur compounds. The percentage of total S + N equivalent deposition as nitrogen describes the proportion of potential acidity that is due to nitrogen deposition.

## Availability of Maps and Data

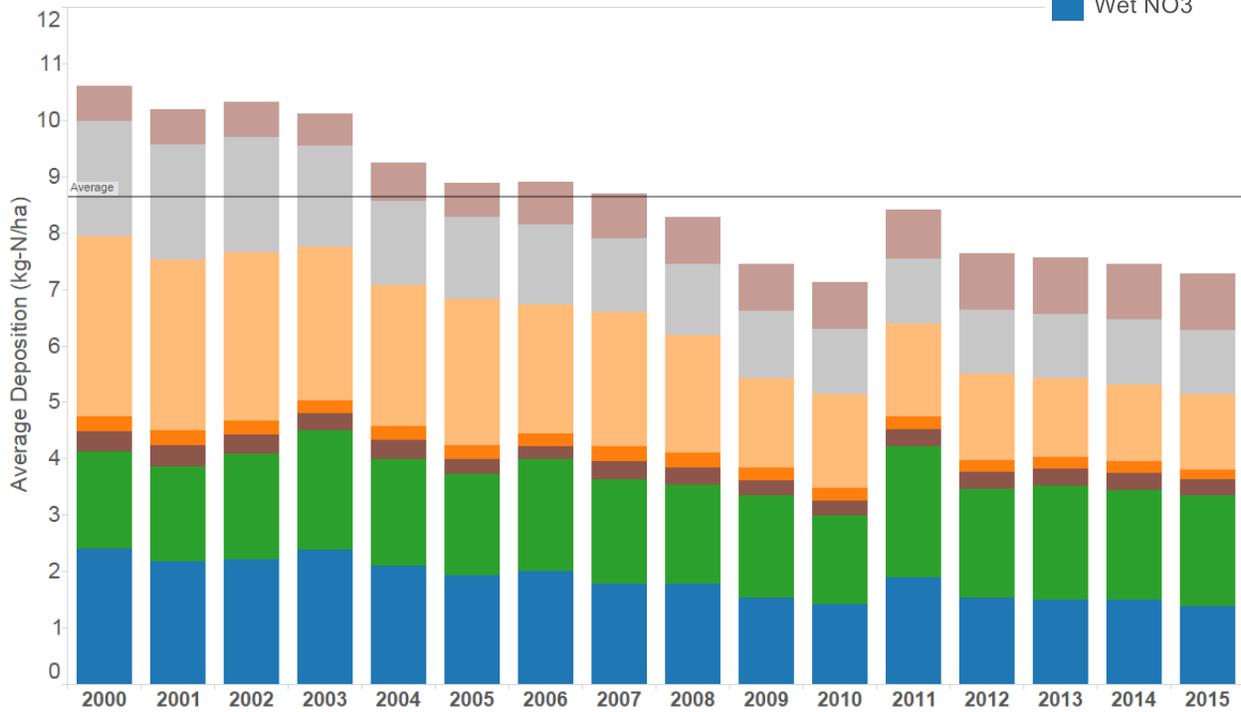

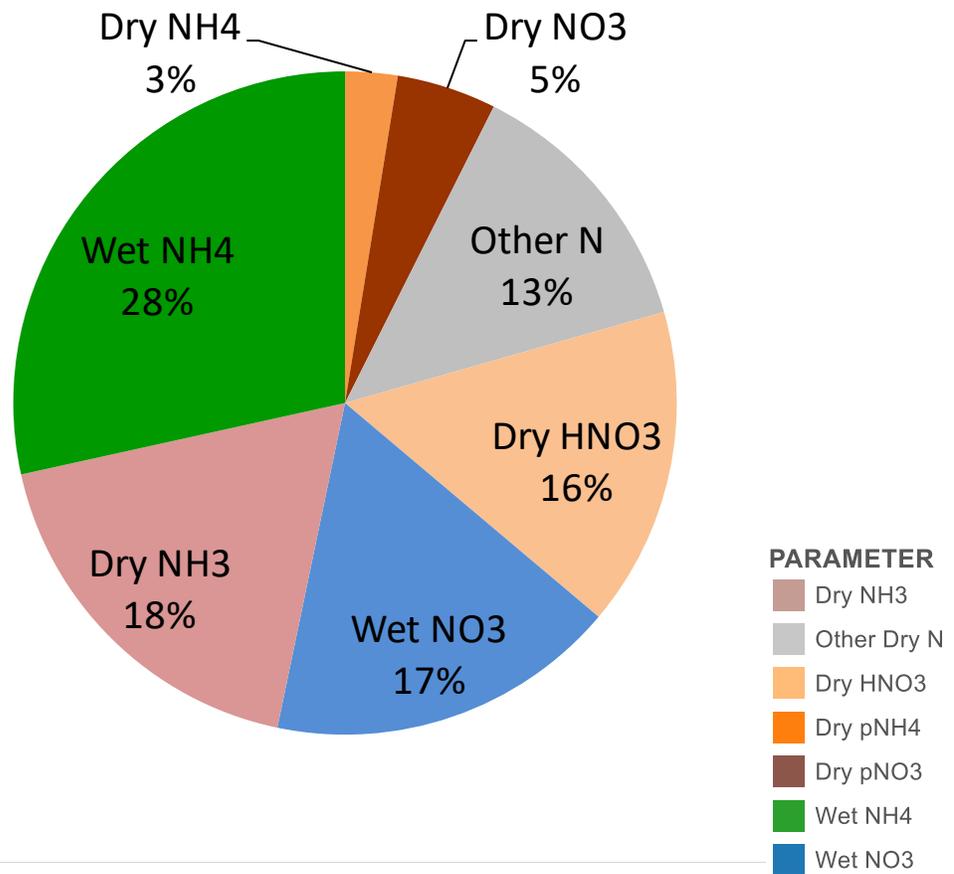

The hybrid maps are available for years 2000-2015 and for select 3-year averages for all components of total sulfur and nitrogen deposition. The most recent version is available as ESRI Grid™ files and maps, which can be downloaded from the NADP website at <http://nadp.isws.illinois.edu/tdepmaps>. This data set will be updated each year as new data, both modeled and measured, become available and as the methodology evolves.

## Use and Limitations

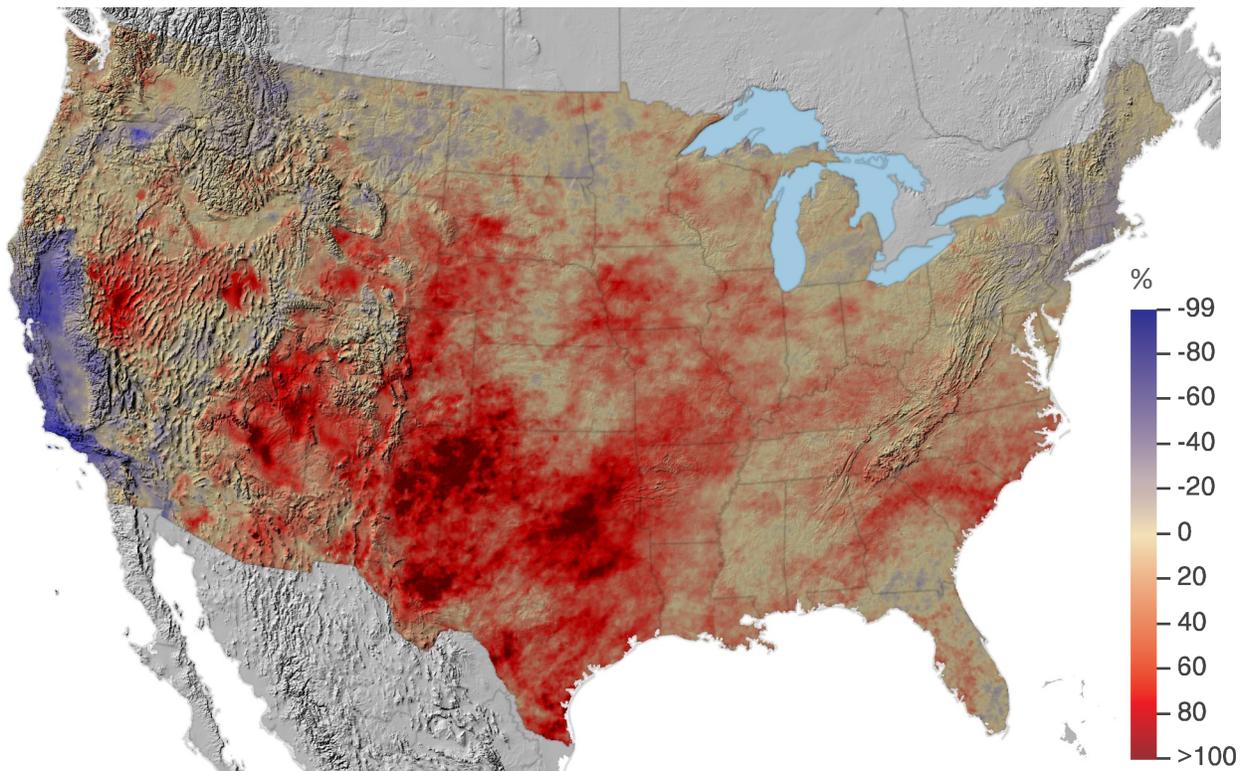

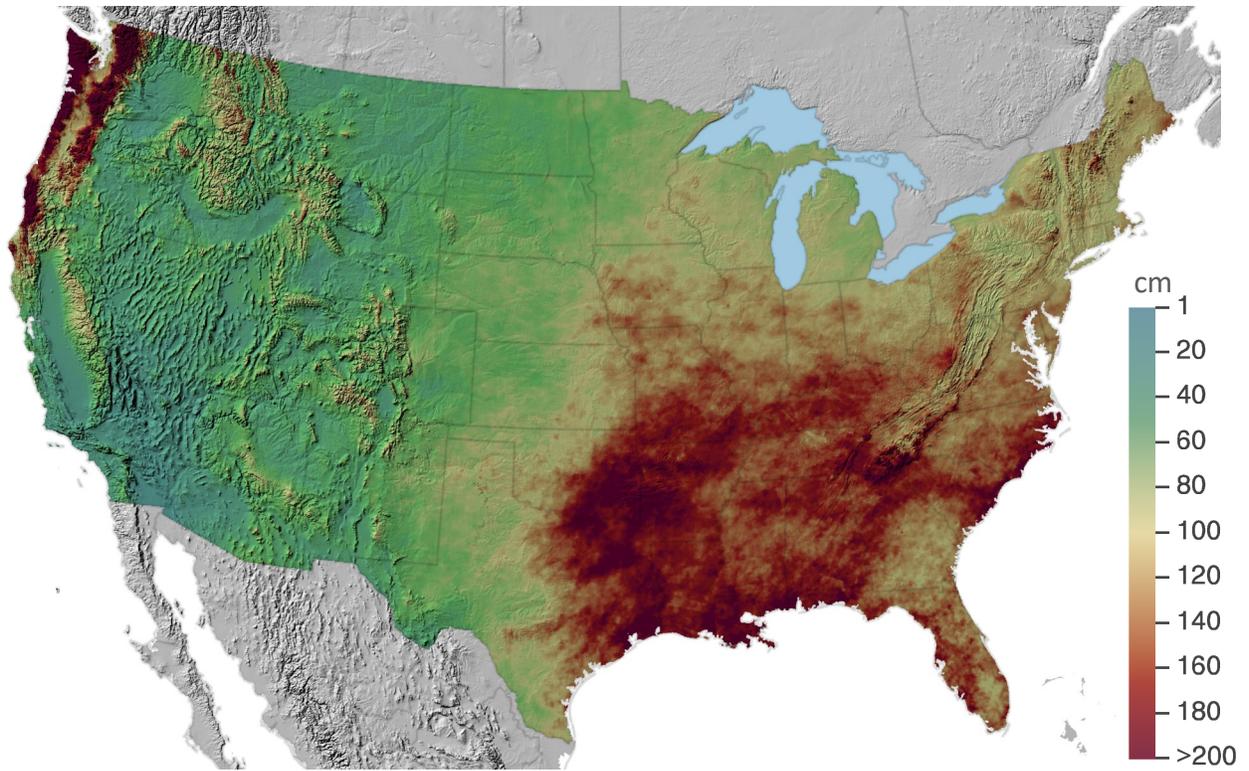

The TDEP maps have been used by the TDEP Science Committee to identify areas of research that are critical to advancing our understanding of accurately estimating total deposition. The maps are also being used by resource managers to assess ecosystem health. Critical load exceedances can be identified by combining maps of total deposition and critical loads. The TDEP maps provide the best available estimates of total deposition based on the most recent information; however, there are limitations, including but not limited to the following:

- Interpolation techniques inherently minimize extreme values, so more variability would be expected if more spatially resolved observations were available for use.
- The use of monitoring data is limited to sites and times that meet network completion criteria to ensure that measurements are representative of actual conditions.
- Discontinuities in temporal and spatial trends at specific locations may occur where monitoring data are intermittent.
- The methodology used to develop the wet deposition grids differs from that used for the NADP network precipitation grids.
- Ammonia data from the NADP Ammonia Monitoring Network (AMoN) and SEARCH are only used for model evaluation and are not included in the development of the concentration surfaces because a method for combining a concentration measurement with a bidirectional flux has not yet been developed.
- There is likely an incomplete characterization of the wet and dry organic nitrogen components due to a lack of measurements resulting in an underestimate of total nitrogen deposition.
- Since the measurement sites used in the method are located primarily in rural areas, deposition in urban areas may not be well represented.
- Occult deposition is poorly understood and may not be accurately characterized in modeling.

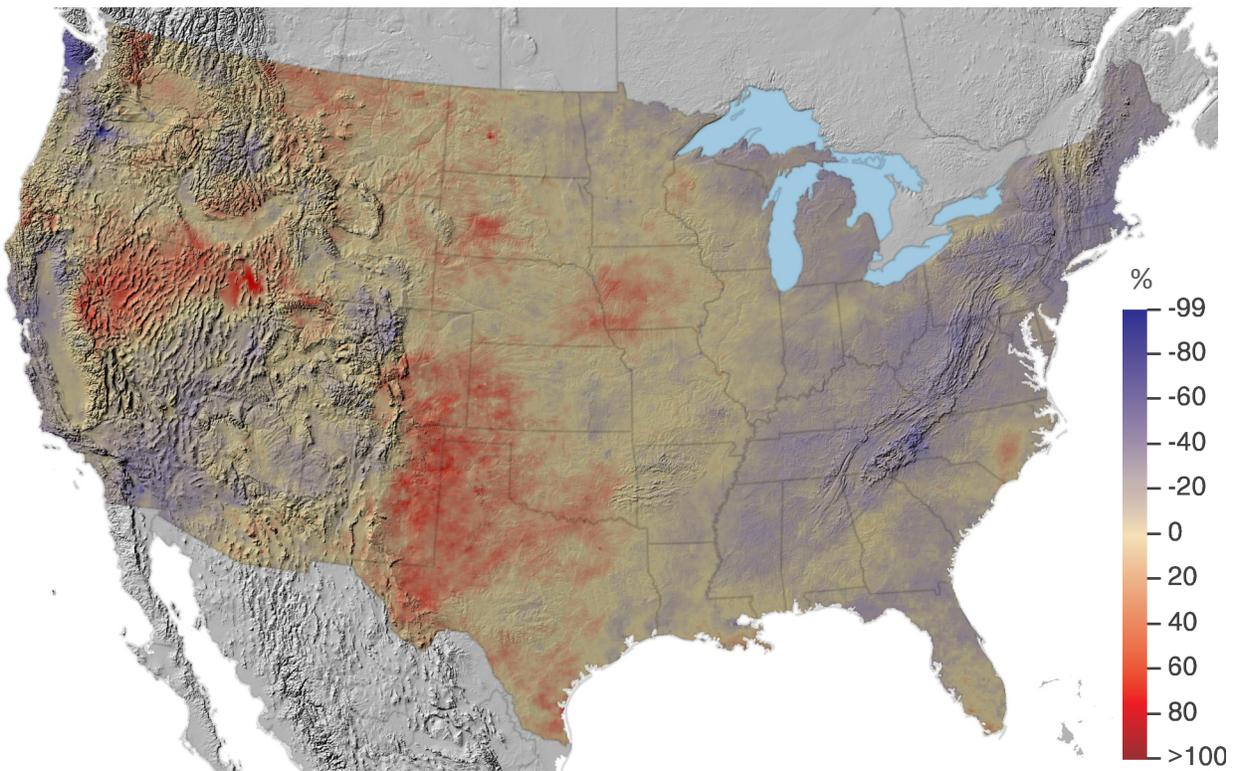

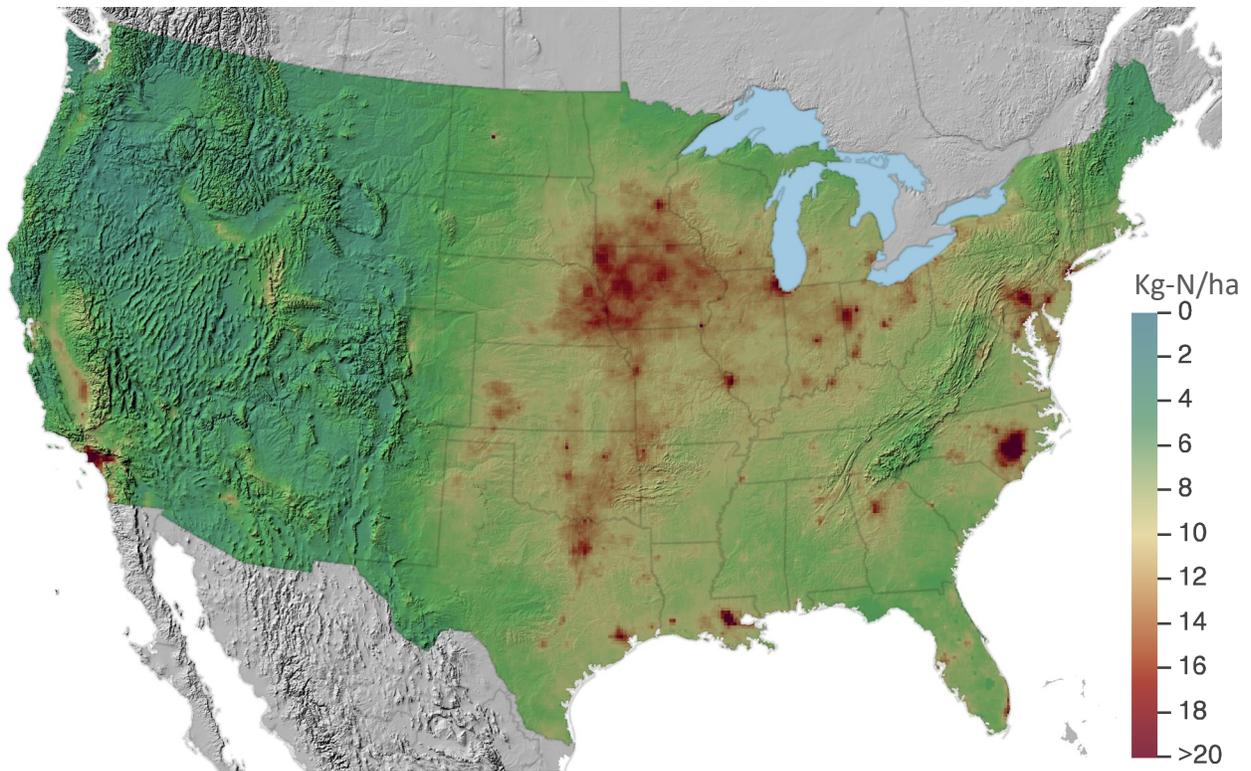

The TDEP Science Committee is open to anyone that wants to participate and meets twice a year. Scientific contributions and collaboration towards this work are welcome. For more information, please contact the Chair or Co-Chair of the TDEP Science Committee (<http://nadp.isws.illinois.edu/committees/tdep/contacts.aspx>).

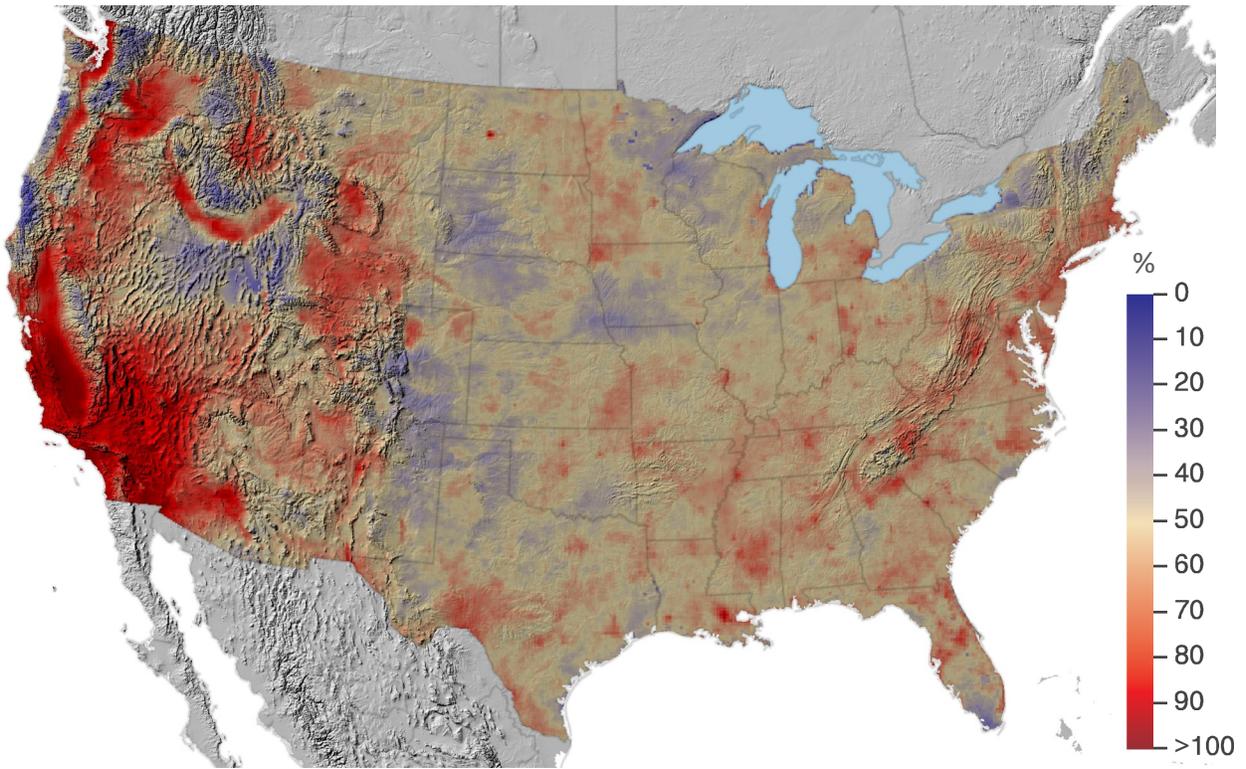

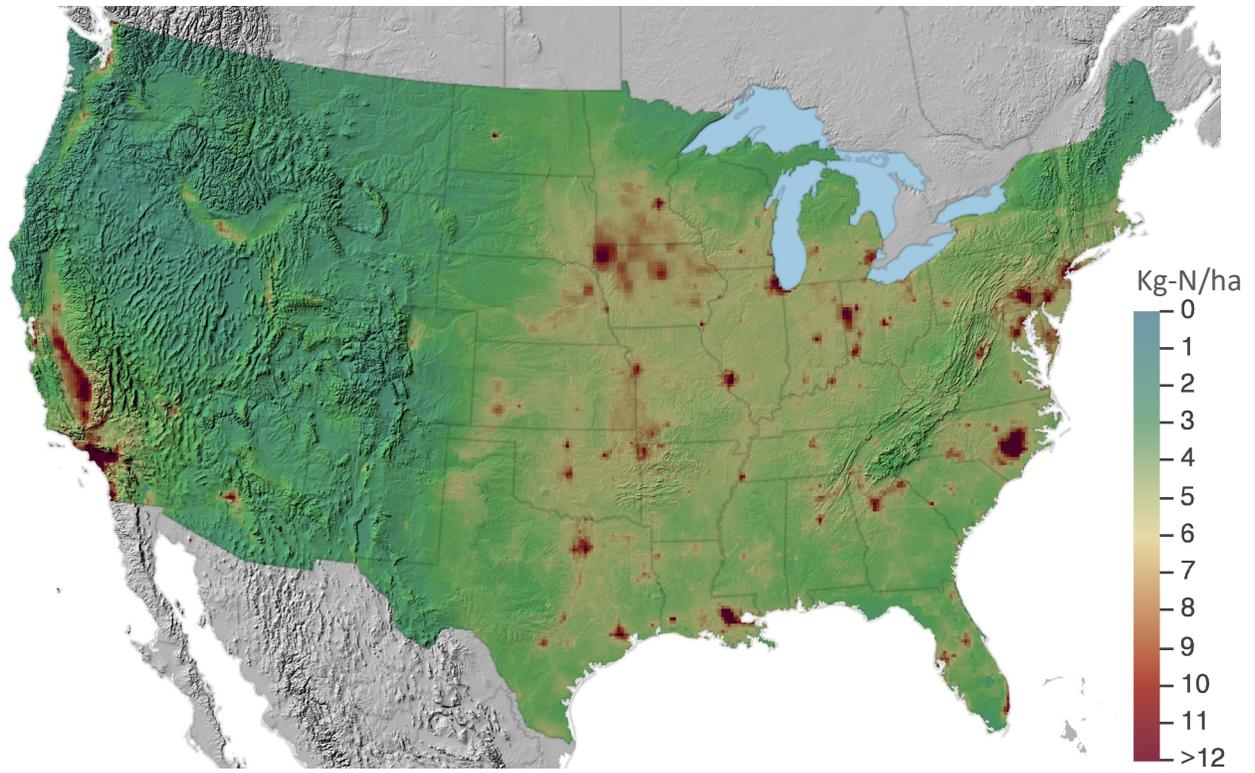

Composition of nitrogen deposition in the US for 2013-2015 (top), and historical average annual total nitrogen deposition at CASTNET sites (bottom).

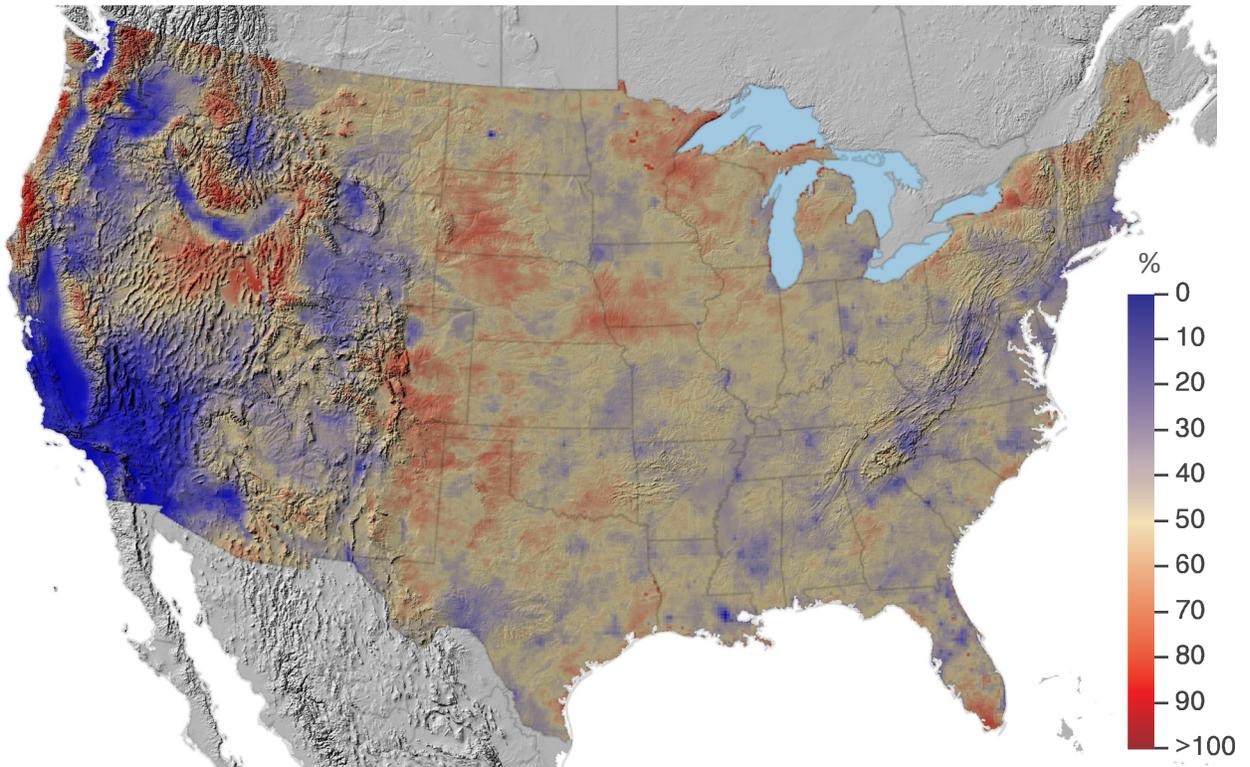

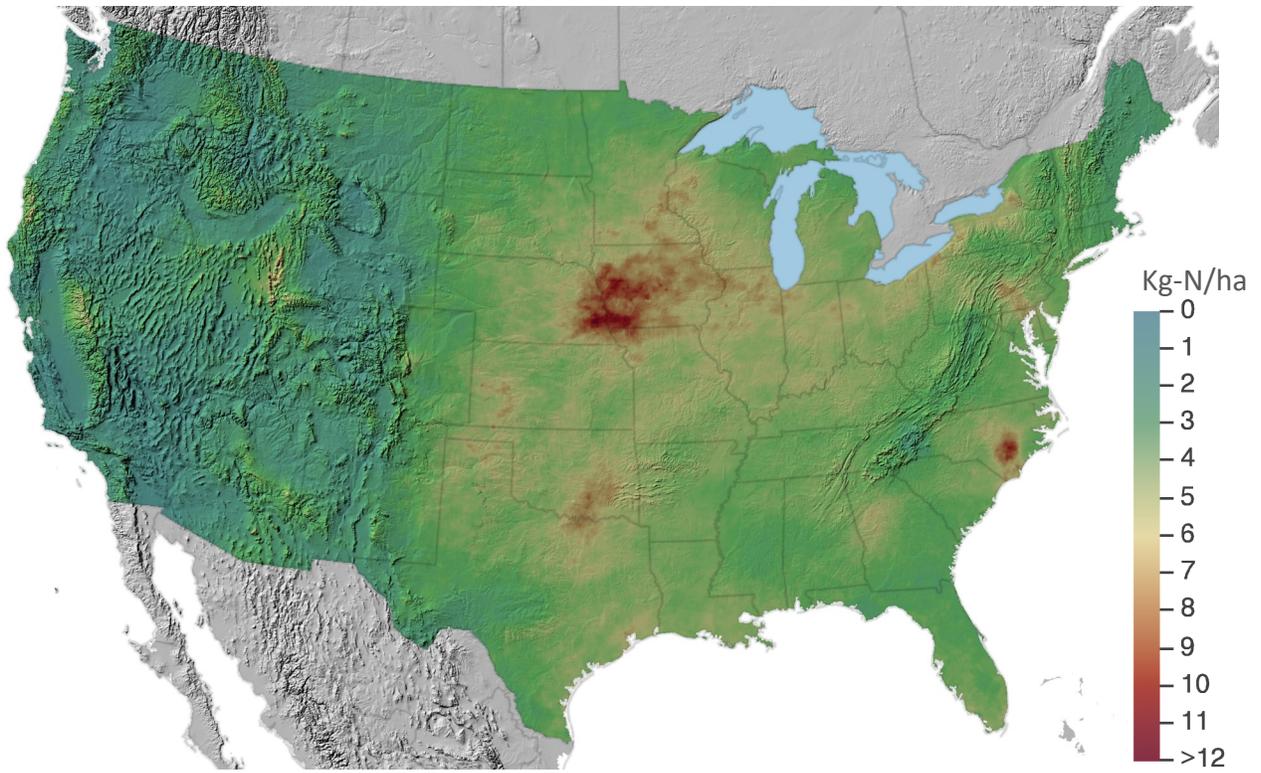

Total annual precipitation in 2015 (top), and percent deviation of 2015 precipitation values compared to the annual average of 2000-2015 (bottom).

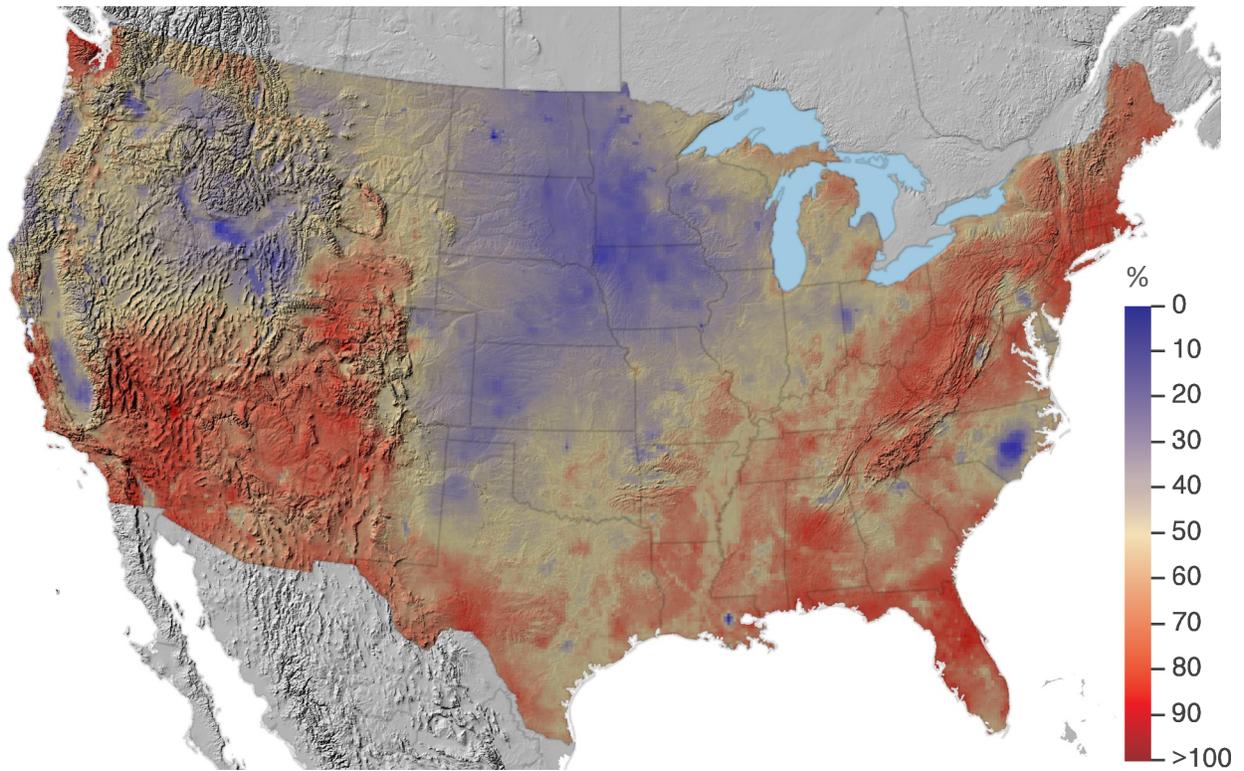

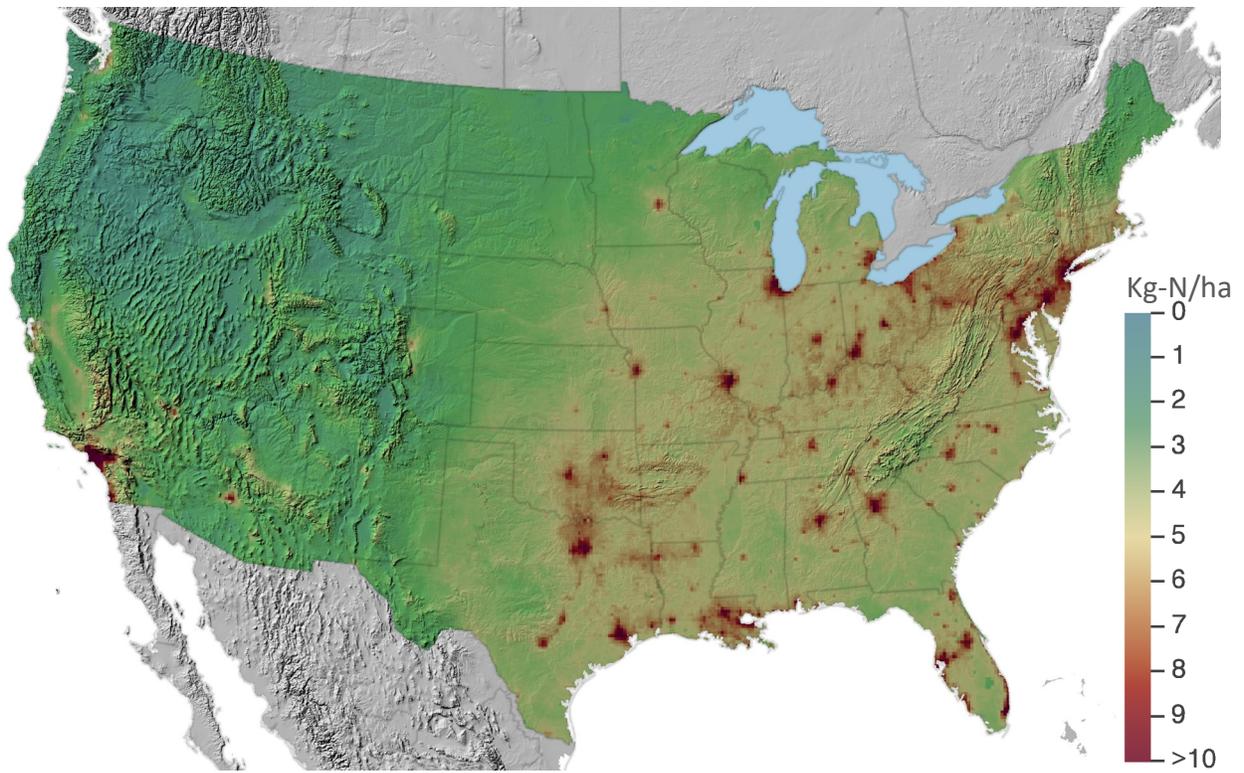

Total nitrogen deposition in 2015 (top), and percent deviation of 2015 nitrogen deposition values compared to the annual average of 2000-2015 (bottom).

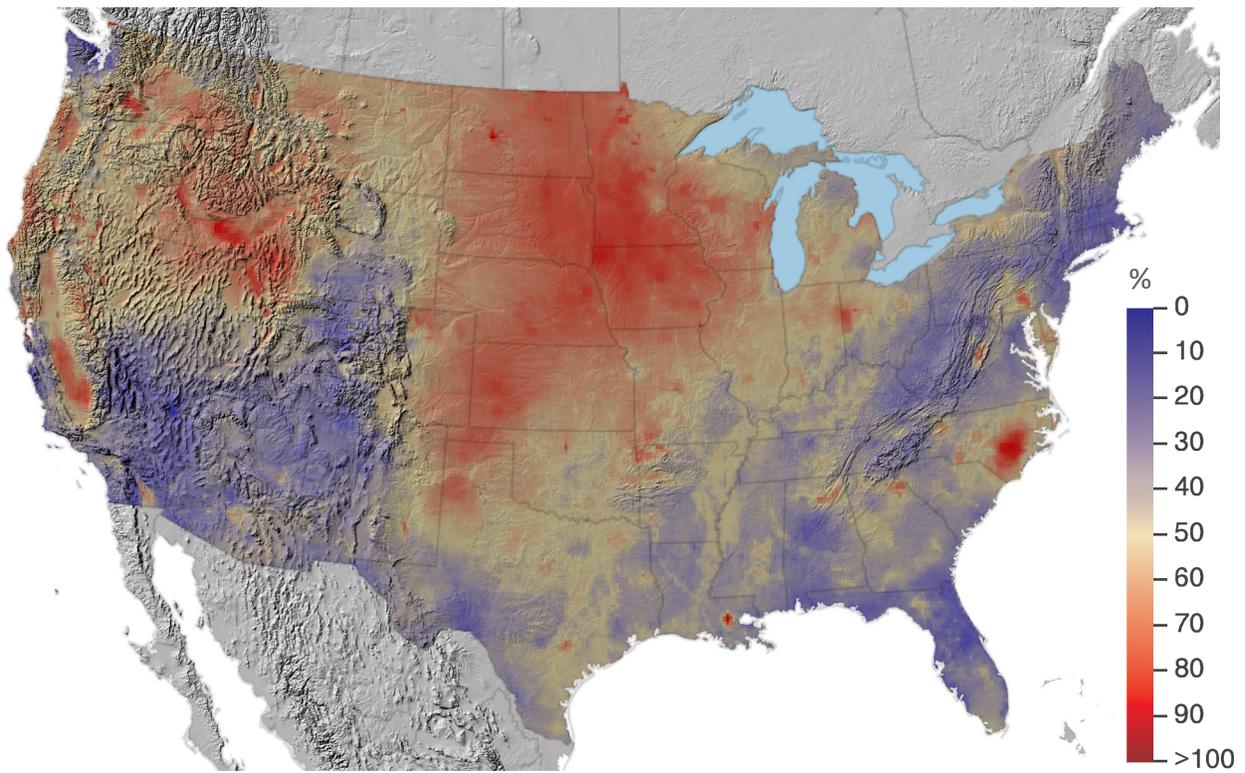

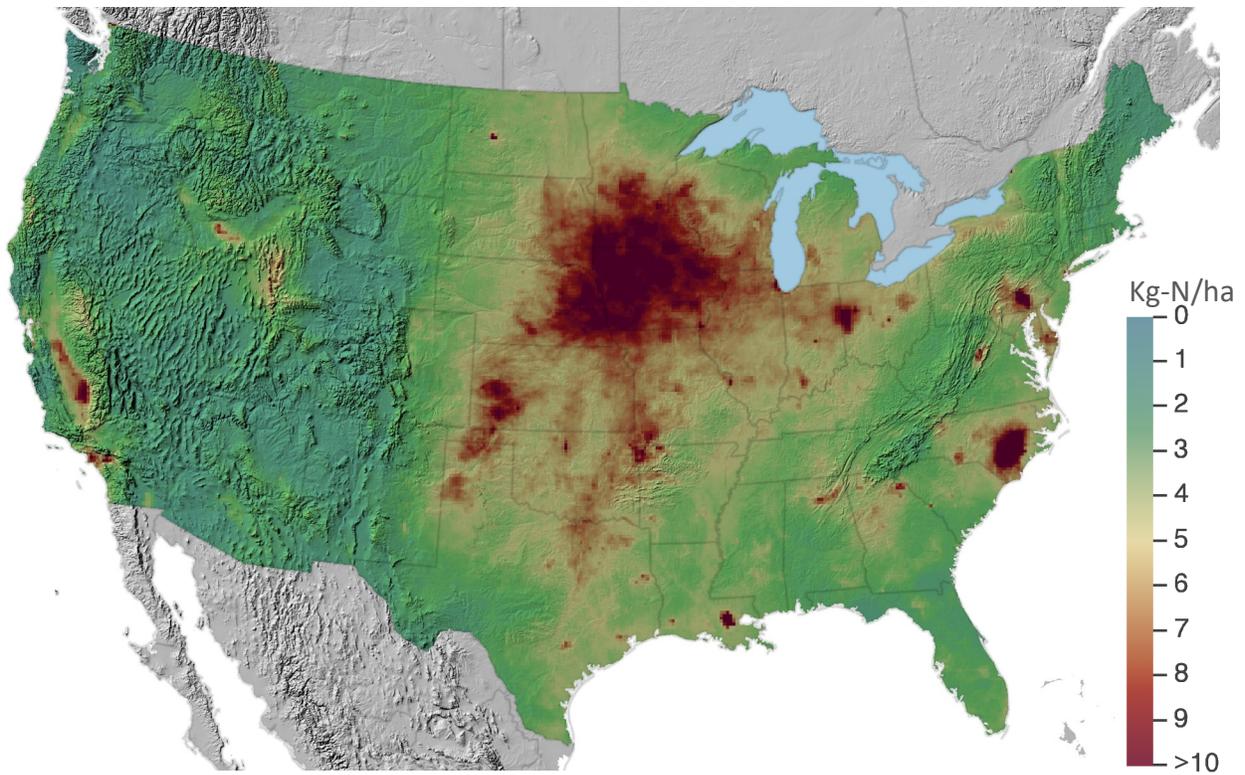

Annual dry nitrogen deposition in 2015 (top), and percent of total nitrogen deposition as dry deposition in 2015 (bottom).

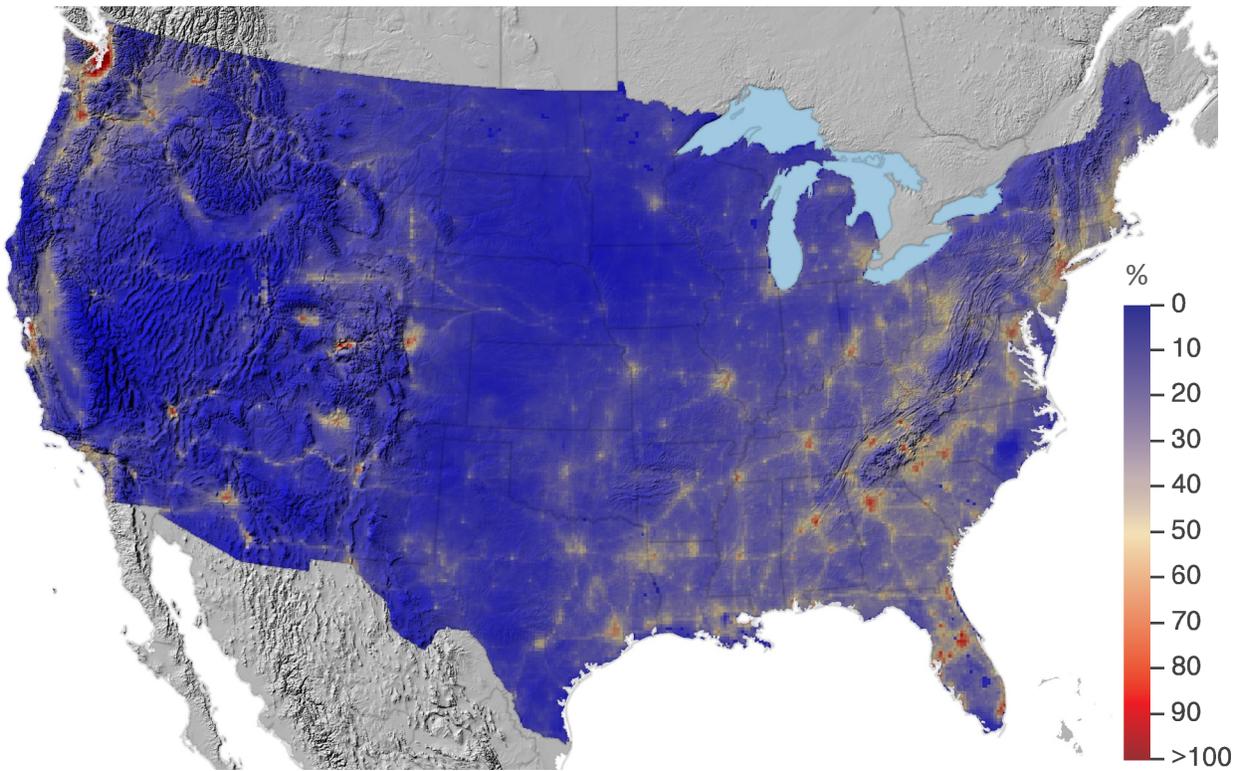

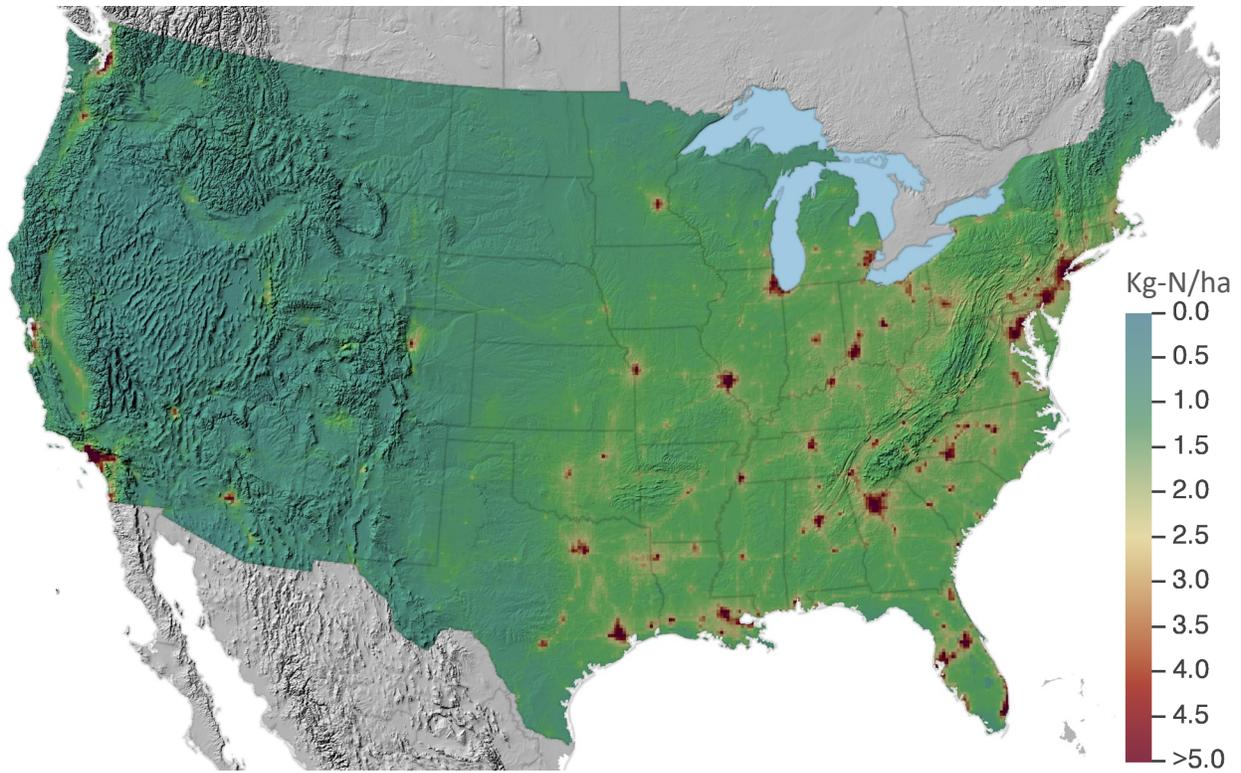

Annual wet nitrogen deposition in 2015 (top), and percent of total nitrogen deposition as wet deposition in 2015 (bottom).

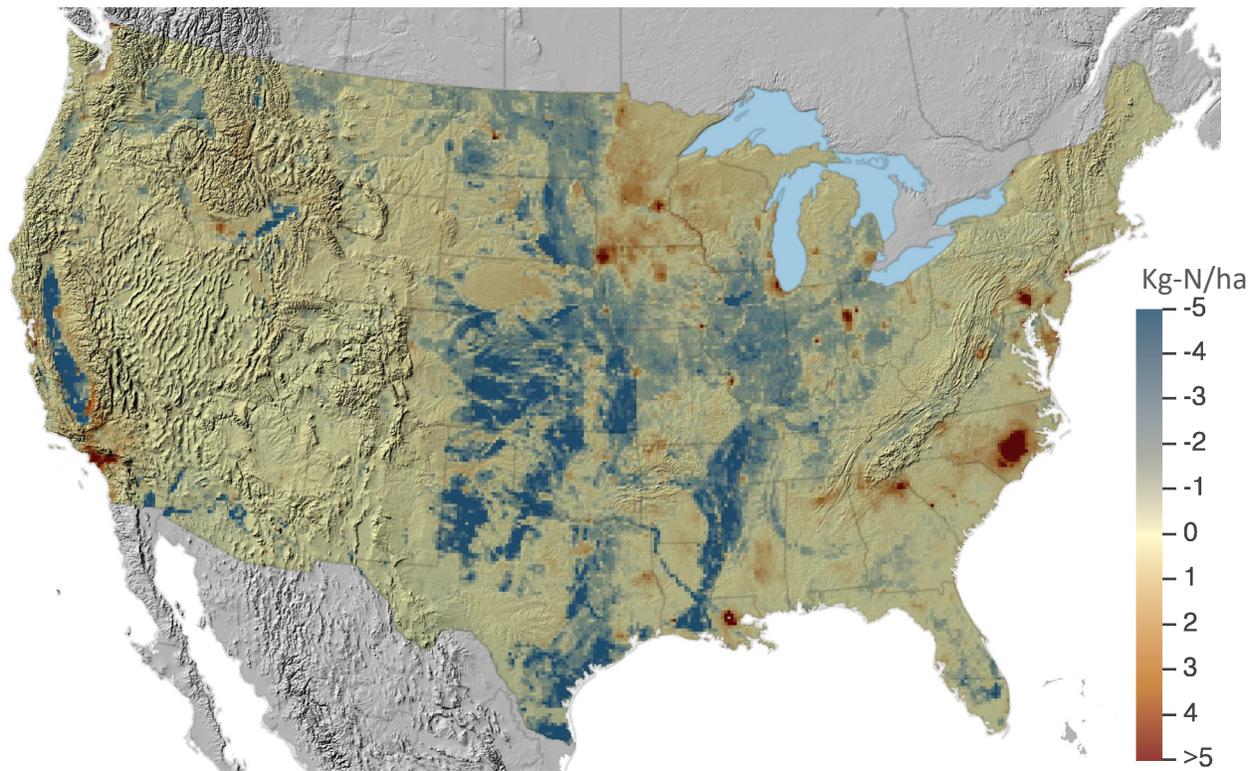

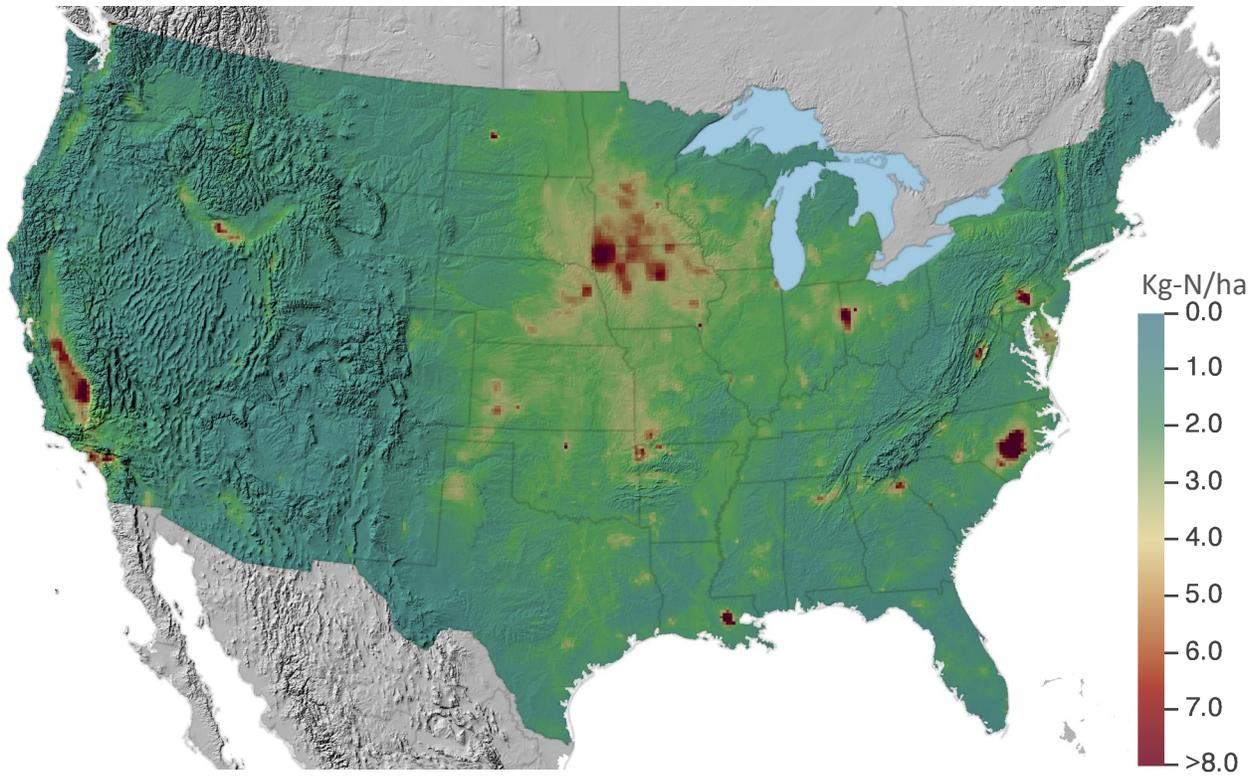

Annual oxidized nitrogen deposition in 2015 (top), and percentage of total nitrogen deposition as oxidized nitrogen in 2015 (bottom).
