ABSTRACT

Total (wet plus dry) atmospheric deposition of nitrogen (N) and sulfur (S) has been estimated for U.S. Forest Service (USFS) lands across the conterminous United States over the past two decades using a variety of methods. These have included wet and dry model estimates derived from the Community Multiscale Air Quality (CMAQ) model of Byun and Schere (2006), interpolations of National Atmospheric Deposition Program (NADP) wet deposition data, Clean Air Status and Trends Network (CASTNET) estimates of dry deposition, and others. Recently, Schwede and Lear (2014) documented a hybrid approach developed by the NADP Total Deposition (TDEP) Science Committee for estimating total N and S deposition. This new approach primarily relies upon measurements of air pollutant concentrations taken from CASTNET and NADP, combined with results of CAMQ simulations. There is a possibility that the USEPA, and perhaps other agencies and researchers, will develop future deposition estimates for policy-relevant assessment based on results from this new TDEP effort. This led Forest Service staff to consider the extent to which earlier estimates of deposition, generated using other methods, differ from the new TDEP estimates. Of particular concern is how these differences might affect estimates of critical load (CL) and associated exceedances. There is a need to compare the new TDEP estimates with those generated using other methods. The research reported here addresses that need. We provide spatial analyses of differences among several commonly used approaches for estimating total (wet plus dry) N and S deposition. Comparisons are made for all national forests and USFS wildernesses in the conterminous United States, averaged over the time period 2000-2012. Individual annual estimates are also available in the project database. Relatively large differences were found between TDEP estimates and those generated using some of the other approaches. These differences varied spatially. Such

differences should be considered in estimating CLs and the extent to which CLs are exceeded under ambient deposition levels on USFS lands and elsewhere.

INTRODUCTION

Regional and national modeling of atmospheric nitrogen (N) and sulfur (S) deposition on U.S. Forest Service (USFS) lands has been an active area of study for the past several decades. Methods have primarily relied on fine-scale spatial interpolation of observed deposition and sophisticated process-level atmospheric modeling conducted at relatively coarse scales. Atmospheric deposition effects studies on USFS-managed lands in the eastern United States have commonly relied on a combination of spatial interpolations of wet deposition (using the Grimm and Lynch (1997) approach) and process modeled dry deposition output from CMAQ to derive estimates of total N and S deposition. A multitude of other approaches for estimating total deposition, including estimates based on throughfall chemistry (cf., Weathers et al. 2006) have also been applied to better understand potential biological effects of air pollution. A hybrid approach was recently developed by the NADP Total Deposition (TDEP) Science Committee to leverage the strengths of the monitoring and modeling approaches where appropriate (Schwede and Lear 2014). The TDEP Science Committee is a broad multi-organizational group consisting of but not limited to the USEPA, USGS, NPS, USFS, NOAA, USFWS, EPRI, university researchers and other industries. The TDEP method is currently being adopted by practitioners requiring a spatial understanding of total N and S deposition at local to national scales. Anecdotal evidence indicates that these new deposition estimates developed using TDEP are substantially different at some locations from those derived using previous approaches.

The project reported here evaluated differences among deposition results derived from some of these various approaches as compared with the newly developed TDEP database. We

quantify and report the magnitude and location of the differences in deposition estimates for all national forest and wildernesses in the contiguous United States in order to provide an understanding of where conclusions from previous deposition effects research are expected to remain robust and where they may be uncertain as a result of large differences in deposition estimates caused by switching to the new TDEP method.

APPROACH

Data Sources

Data sources used as the basis for this model comparison are provided in Table 1. Wet deposition estimates were taken from two sources, each based on spatial interpolations of NADP wet deposition measurements: interpolations performed by NADP and interpolations performed for the USFS by Jeffrey Grimm, using the approach of Grimm and Lynch (1997). Grimm’s interpolations were only available for the eastern United States; other databases were available across the country. Dry deposition estimates were taken from CASTNET and CMAQ. Dry deposition estimates from CASTNET are based on measurements of air pollutant concentrations at CASTNET monitoring sites and assumed deposition velocities which were keyed to vegetation types at the locations of the monitoring sites. CMAQ modeling is described in Byun and Schere (2006).

Table 1. Data sources for wet and dry atmospheric deposition of N and S

Data Filtering

CASTNET dry deposition estimates were filtered so as to only include sites for which there were estimates of N and S dry deposition for at least five years during the comparison period 2000-2012. This step removed six monitoring sites from consideration. For the remaining 87 CASTNET sites that were included in our analyses, values that were missing from the database were substituted as follows:

- If missing years were all at either the beginning or end of the record, then an average of the most recent two years of data was used to fill missing values
- If missing years occurred in the middle of the record, available data for the years that bracketed the data gap were averaged and used to fill the missing values

A nearest neighbor analysis was performed to identify the nearest CASTNET site to each of the interpolated NADP wet deposition grid cells (~2.3 km). These results were used to generate CASTNET dry deposition grids for each year at the same resolution as the interpolated NADP wet deposition data.

Data Analysis

Analyses were conducted to compare TDEP model estimates of N and S deposition with estimates generated using other approaches. Differences between TDEP deposition and other deposition datasets were expressed as both absolute and percent differences, as described below:

- Absolute difference was calculated as (TDEP - comparative dataset)
- Percent difference was calculated as $((\text{TDEP} - \text{comparative dataset}) / \text{TDEP}) * 100$

Deposition units are reported as kg/ha/yr of N or S. Analyses were also conducted to explain differences in deposition that might be attributable to differences in elevation and precipitation.

Comparative Site Locations

Locations of national forests and USFS wildernesses in the conterminous U.S. included in this analysis are shown in Figure 1. Results of the various deposition estimates were generated across the landscape. Annual estimates of deposition available during the period 2000 - 2012 were averaged and are presented here. Those results were evaluated spatially and presented as a series of maps. Distributions of deposition values (and comparisons with TDEP) within each national forest and USFS wilderness were also calculated and presented in tabular format in the Appendix.

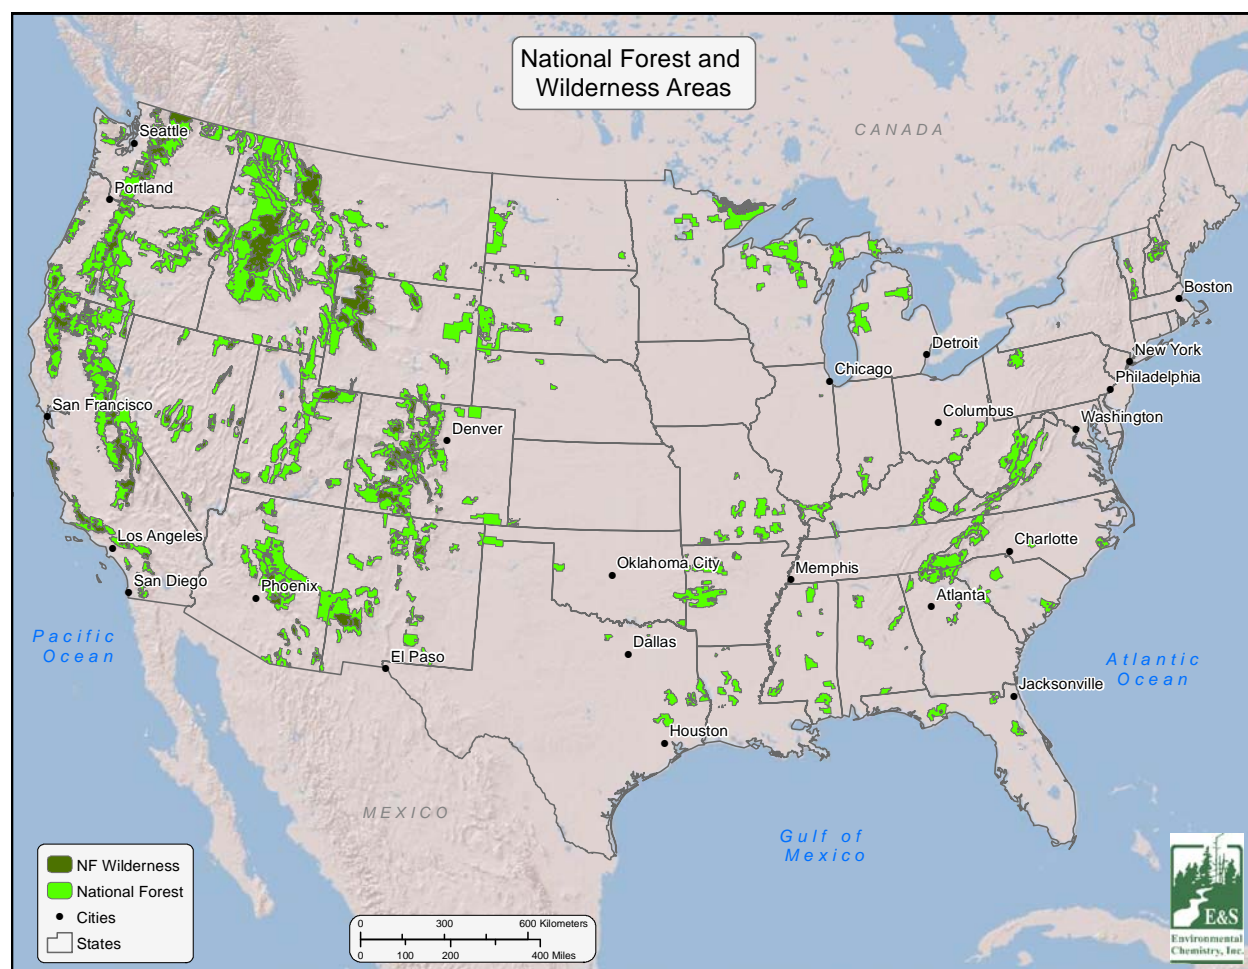

Figure 1a. Locations of national forests and relatively large wildernesses considered in this study.

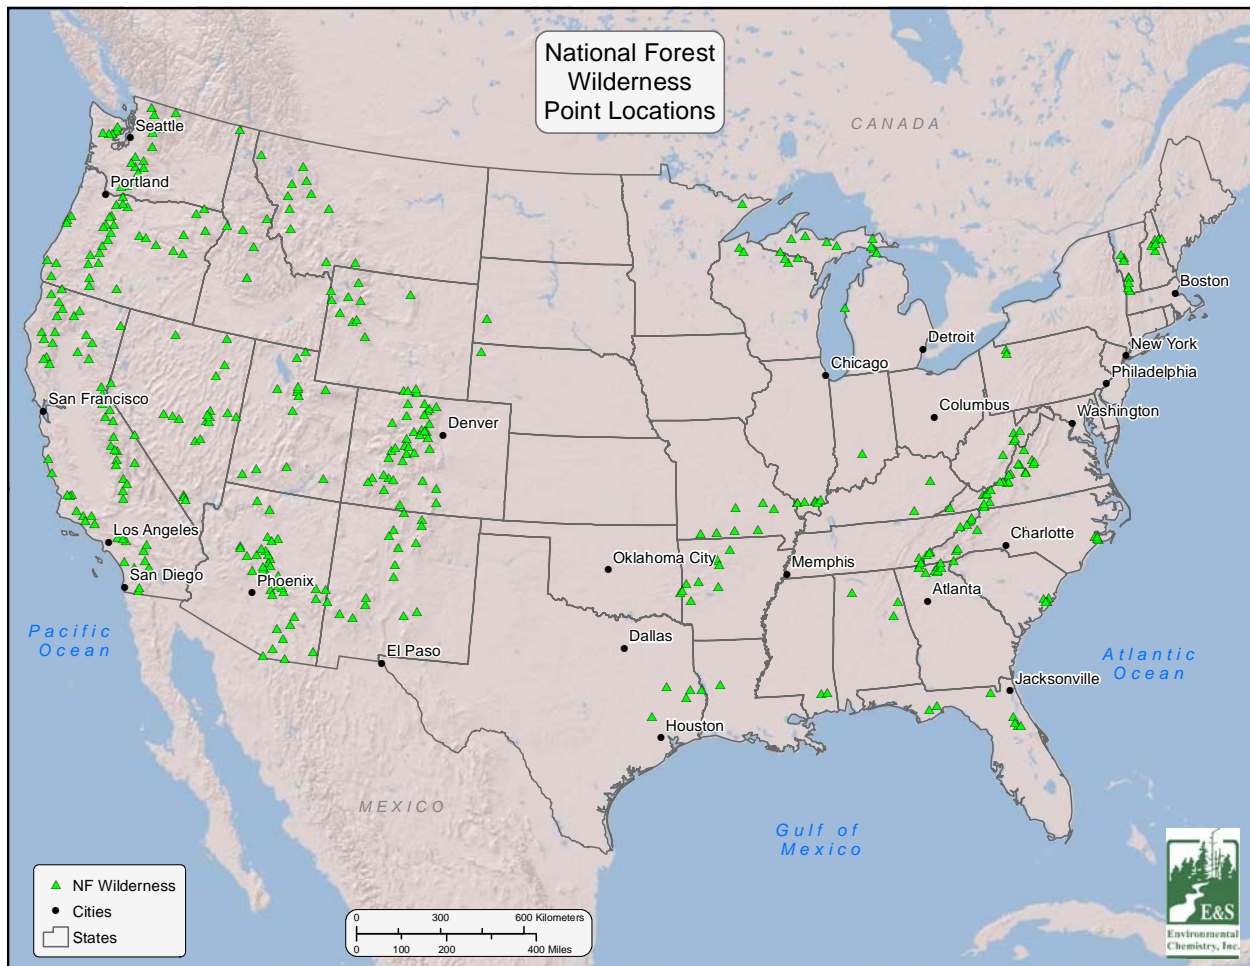

Figure 1b. Centroids of national forest wildernesses considered in this study.

RESULTS

Comparisons Across Methods

Results were partitioned into sections to show the comparisons between TDEP and the various other deposition estimation methods considered in this analysis. In the first such section, TDEP deposition results for N and S are presented first, followed by results for NADP wet plus CASTNET dry, the absolute difference between TDEP and NADP-wet plus CASTNET-dry, and the percent difference between TDEP and NADP-wet plus CASTNET-dry deposition.

Comparisons with other methods are presented in similar fashion, whereby the approach being compared with TDEP is presented first, followed by the absolute difference between the two approaches, and then the percent difference between the two approaches. At locations where TDEP results are higher, the absolute and percent differences are represented as positive values; where TDEP results are lower, the differences are represented as negative values.

Comparison with Interpolated NADP Wet Deposition Plus CASTNET Dry Deposition

Estimates of total N deposition generated from TDEP (Figure 2) showed highest values (> 15 kg N/ha/yr) at scattered locations, mainly in the eastern and northcentral United States. Lowest N deposition estimates occurred in the western United States and northern Maine. Large sections of the eastern United States showed estimated total N deposition higher than 10 kg N/ha/yr using this approach.

Estimates of total S deposition generated from TDEP were highest in a band from the Midwest through Pennsylvania. Total S deposition was relatively low (< 2 kg S/ha/yr) throughout most of the western United States (Figure 3). Nearly the entire eastern United States received more than 5 kg S/ha/yr of total S deposition based on TDEP.

Total N deposition estimates generated from interpolated NADP wet N deposition and CASTNET dry N deposition were relatively low (Figure 4). In the western United States, the estimates of total N deposition were less than 5 kg N/ha/yr at almost all locations; in the eastern United States, estimated NADP + CASTNET total N deposition was between 5 and 10 kg N/ha/yr throughout much of the north and mostly less than 5 kg N/ha/yr in the south (Figure 4). Total S deposition estimates generated from NADP plus CASTNET only exceeded 15 kg S/ha/yr in a small area in and near Ohio (Figure 5). Much of the eastern United States received an estimated 5-10 kg S/ha/yr, with lower values in northern New England and throughout Florida.

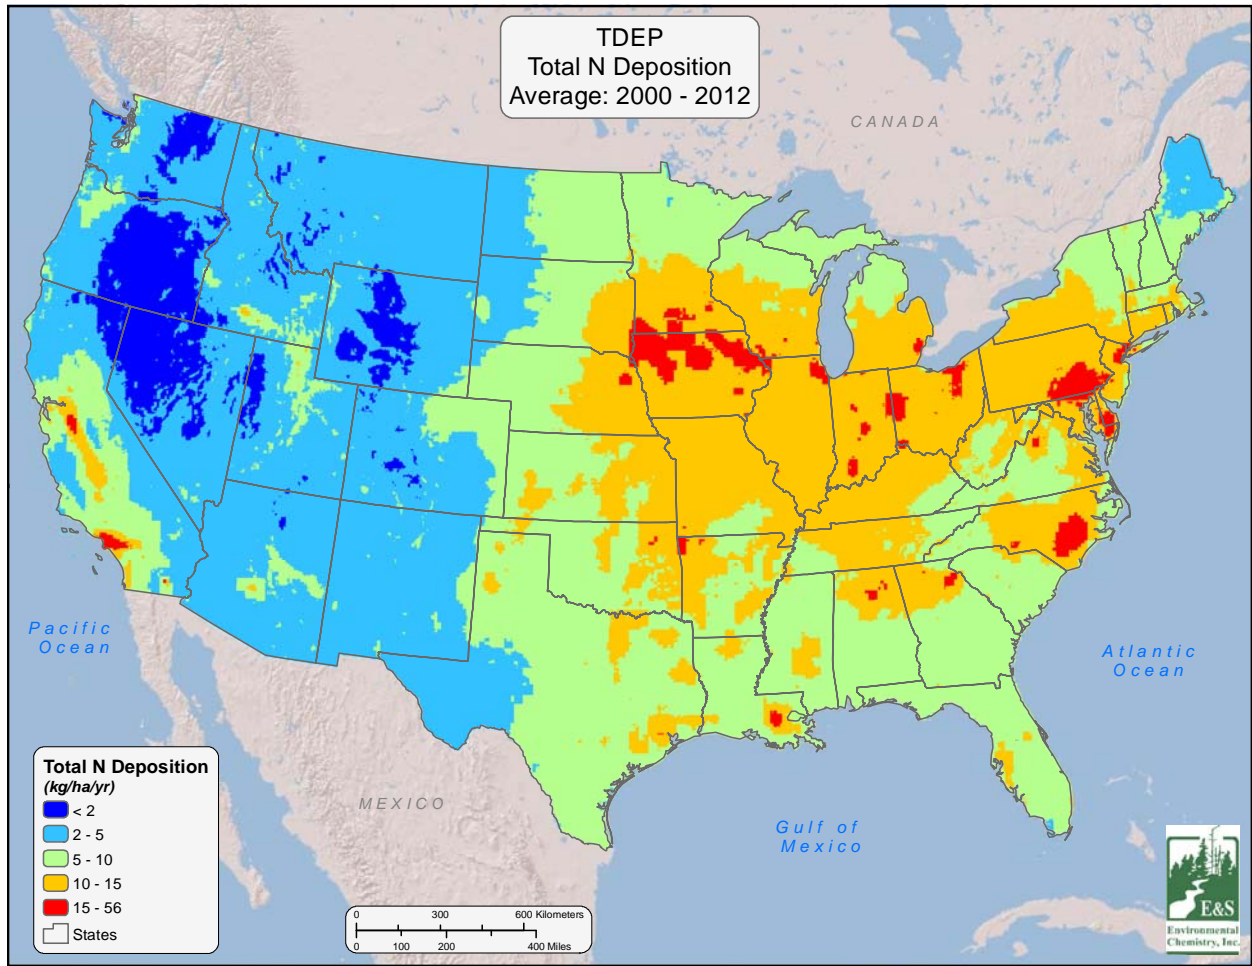

Figure 2. TDEP average annual (2000 – 2012) total N deposition

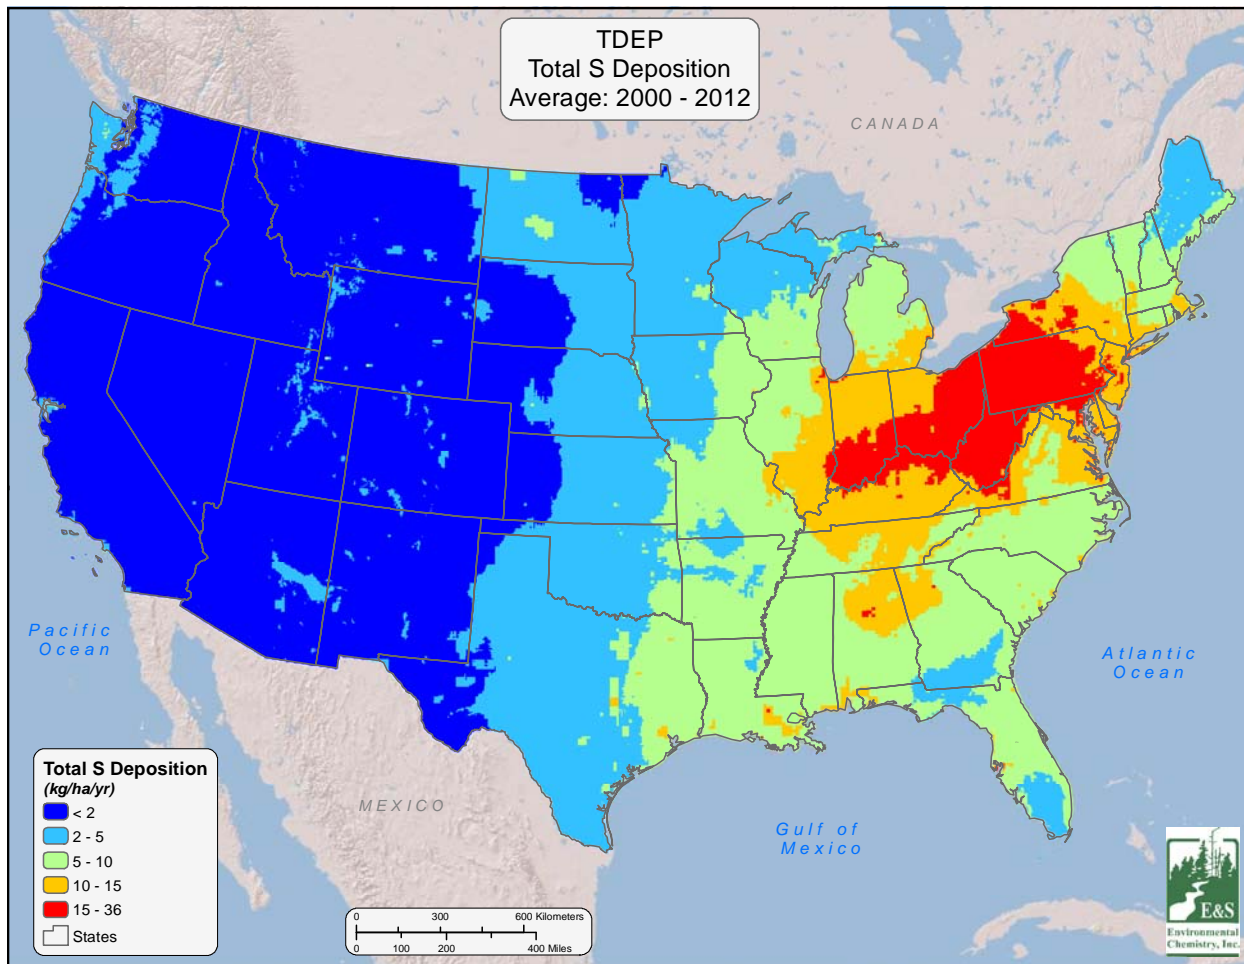

Figure 3. TDEP average annual (2000 – 2012) total S deposition.

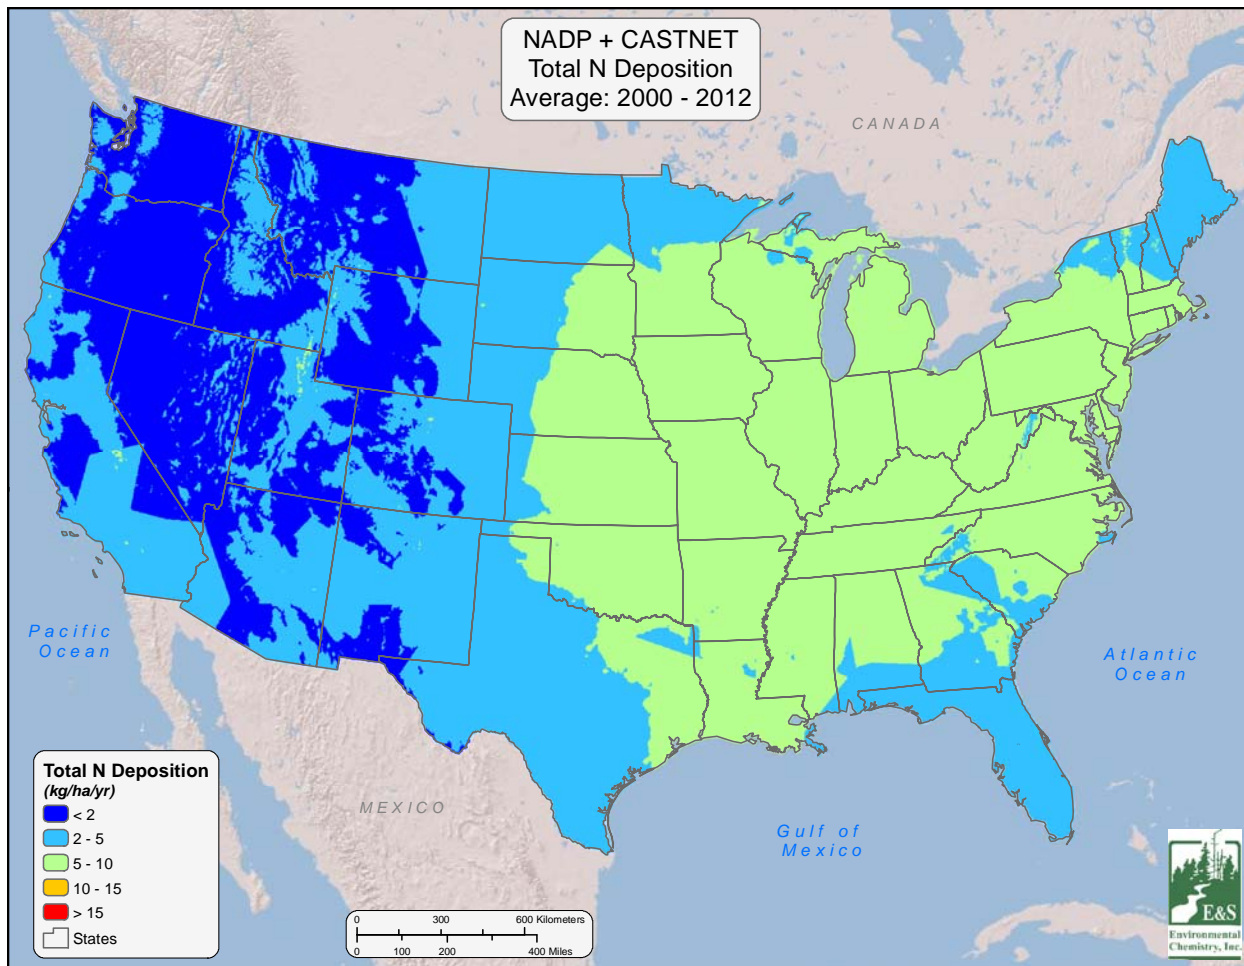

Figure 4. NADP wet + CASTNET dry average annual (2000 – 2012) total N deposition.

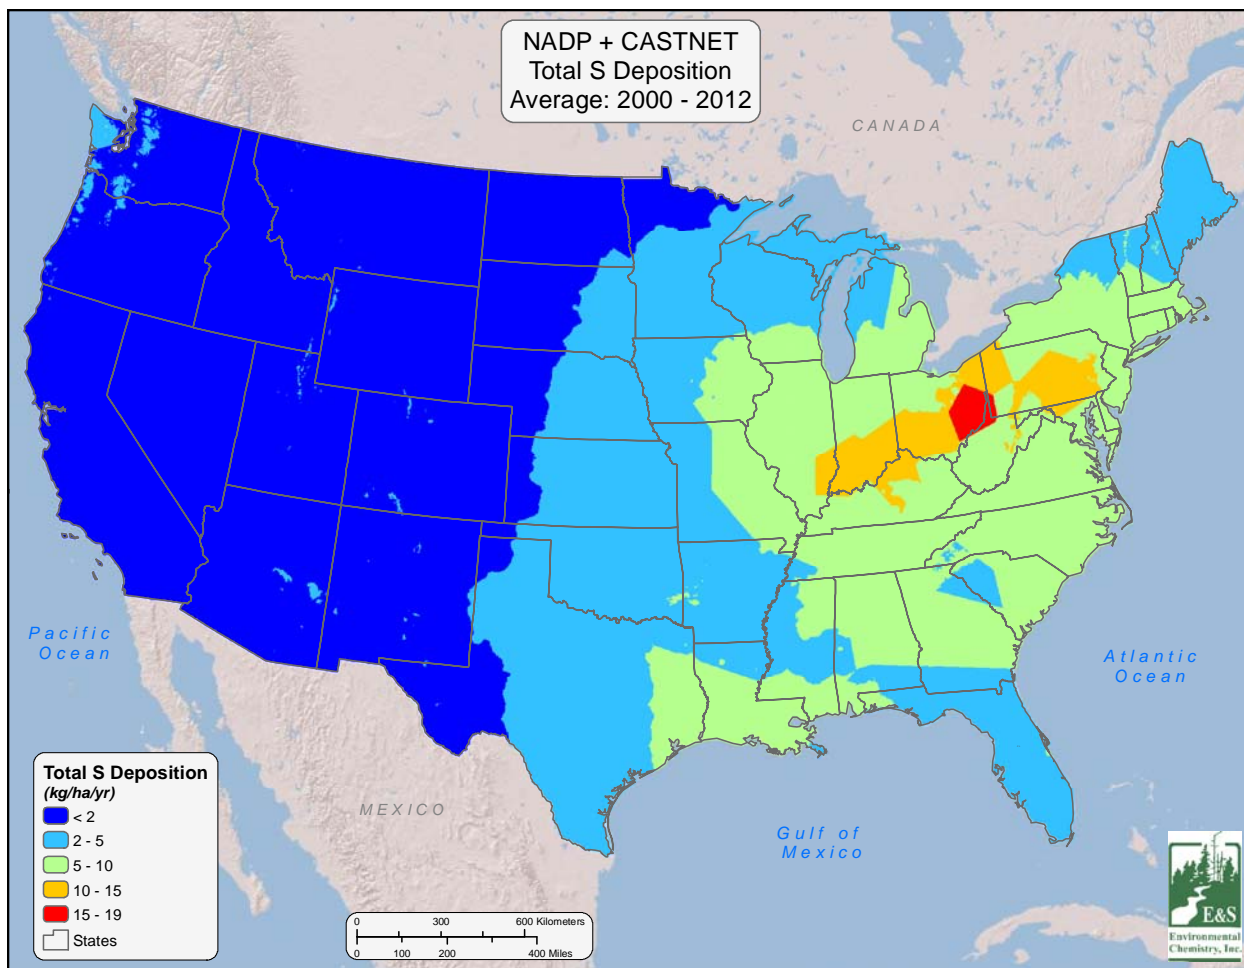

Figure 5. NADP wet + CASTNET dry average annual (2000 – 2012) total S deposition.

Large portions of the western United States showed little absolute difference (-1 to +1 kg N/ha/yr) between the two approaches for total N deposition (Figure 6). Elsewhere, TDEP estimates of total N deposition were consistently higher than NADP plus CASTNET estimates, in many places by more than 4 kg N/ha/yr. Similarly, throughout most of the western United States, there was little absolute difference (-1 to +1 kg S/ha/yr) between the approaches for estimating total S deposition (Figure 7). In much of the eastern United States, the absolute differences for S deposition were more pronounced, in many places by more than 4 kg S/ha/yr. In nearly all cases, the absolute differences were positive, indicating that estimates were higher for TDEP as compared with NADP wet plus CASTNET dry.

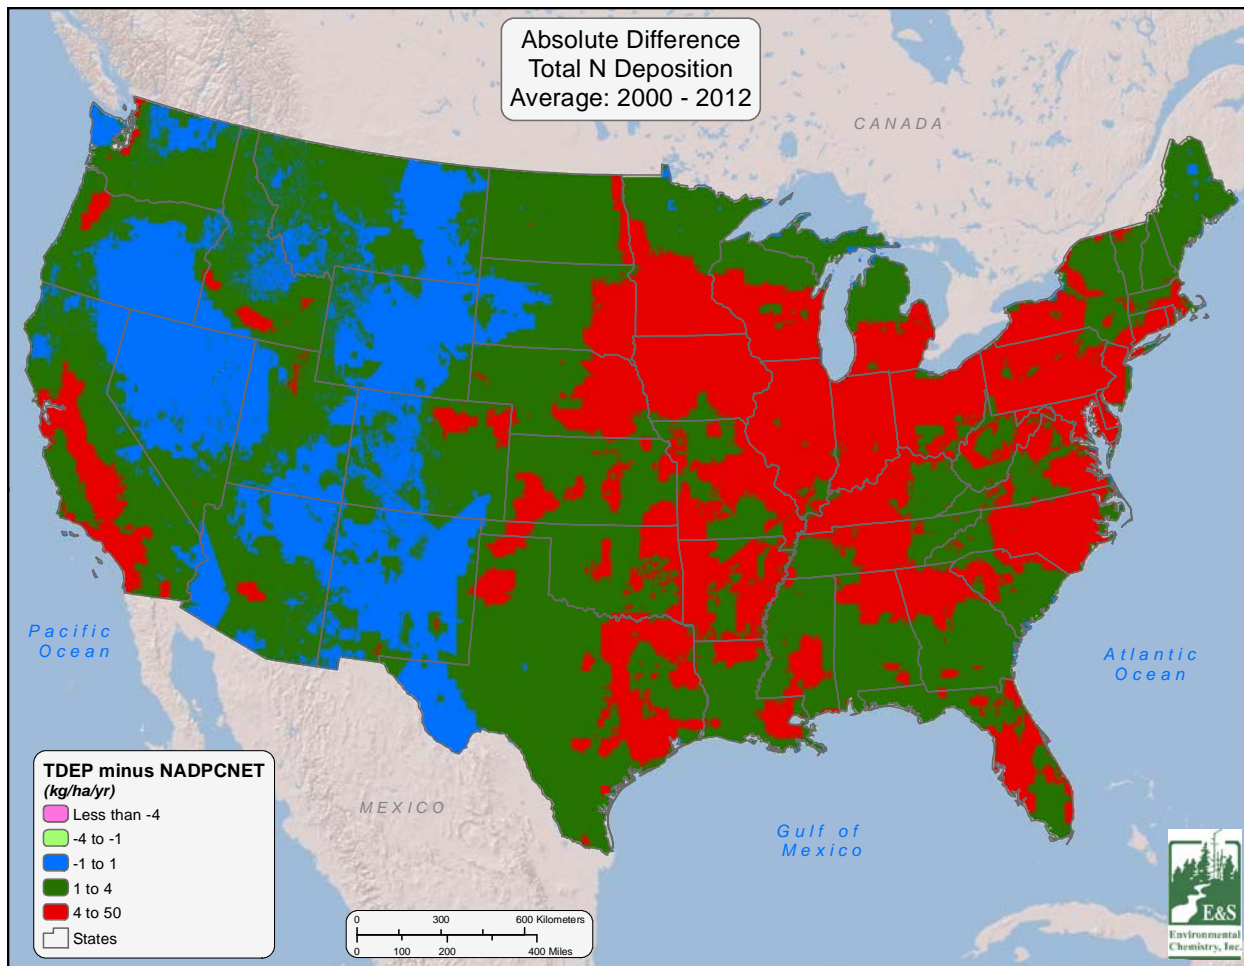

Figure 6. Absolute difference between average annual (2000 – 2012) TDEP and NADP wet + CASTNET dry (NADPCNET) total N deposition.

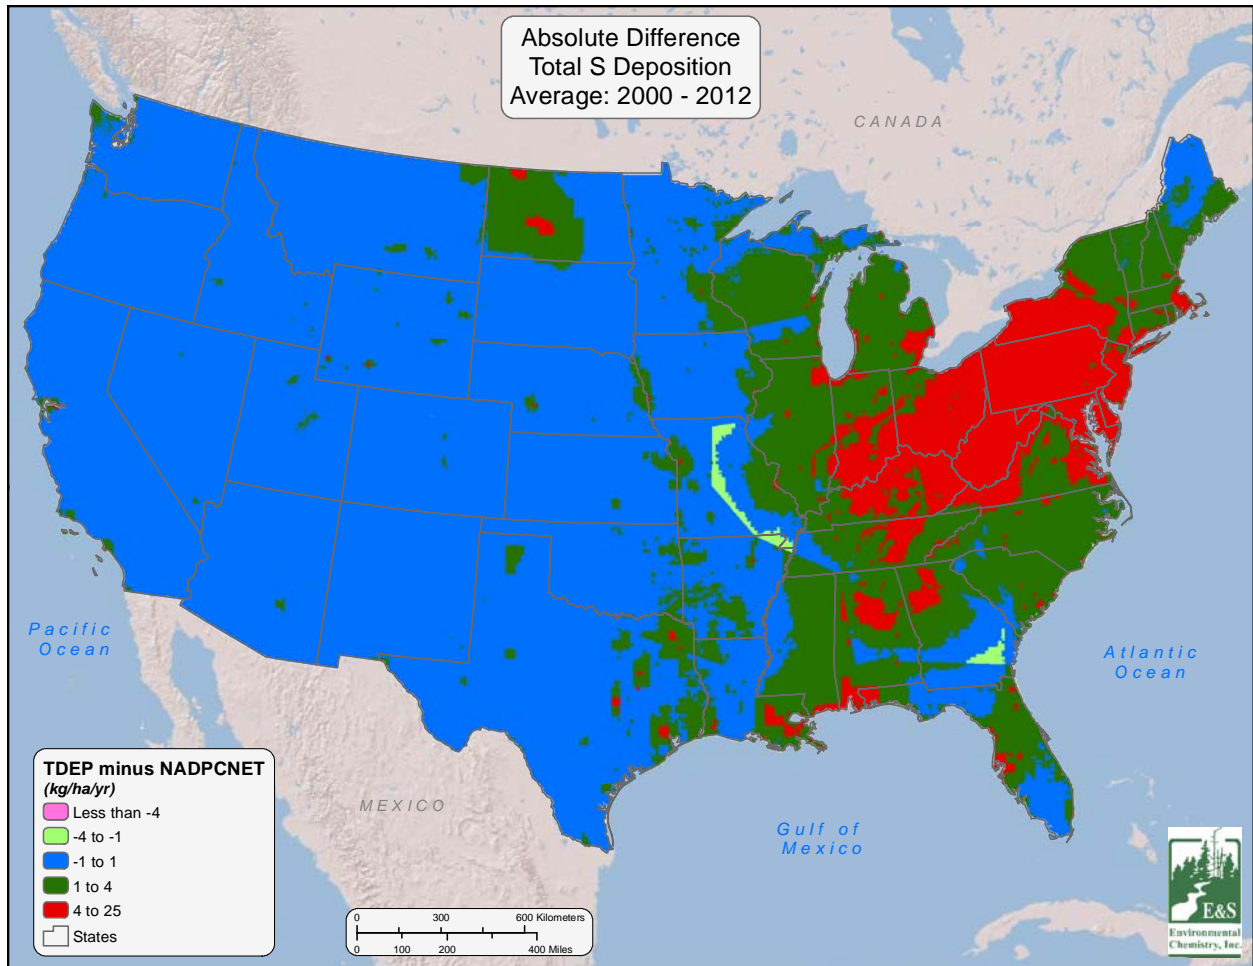

Figure 7. Absolute difference between average annual (2000 – 2012) TDEP and NADP wet plus CASTNET dry total S deposition.

Mapped values for percent differences between TDEP and NADP plus CASTNET were substantial (commonly > 15%; Figure 8). In virtually all cases, the percent difference was positive, indicating higher values for TDEP. Results for the percent difference in estimates for total S deposition (Figure 9) showed generally similar patterns, albeit not as pronounced. Relatively few locations showed TDEP estimates lower than NADP plus CASTNET estimates. At most locations, TDEP estimates of total S deposition were more than 15% higher, in some places more than 50% higher. Thus, differences between estimates of total N and S deposition

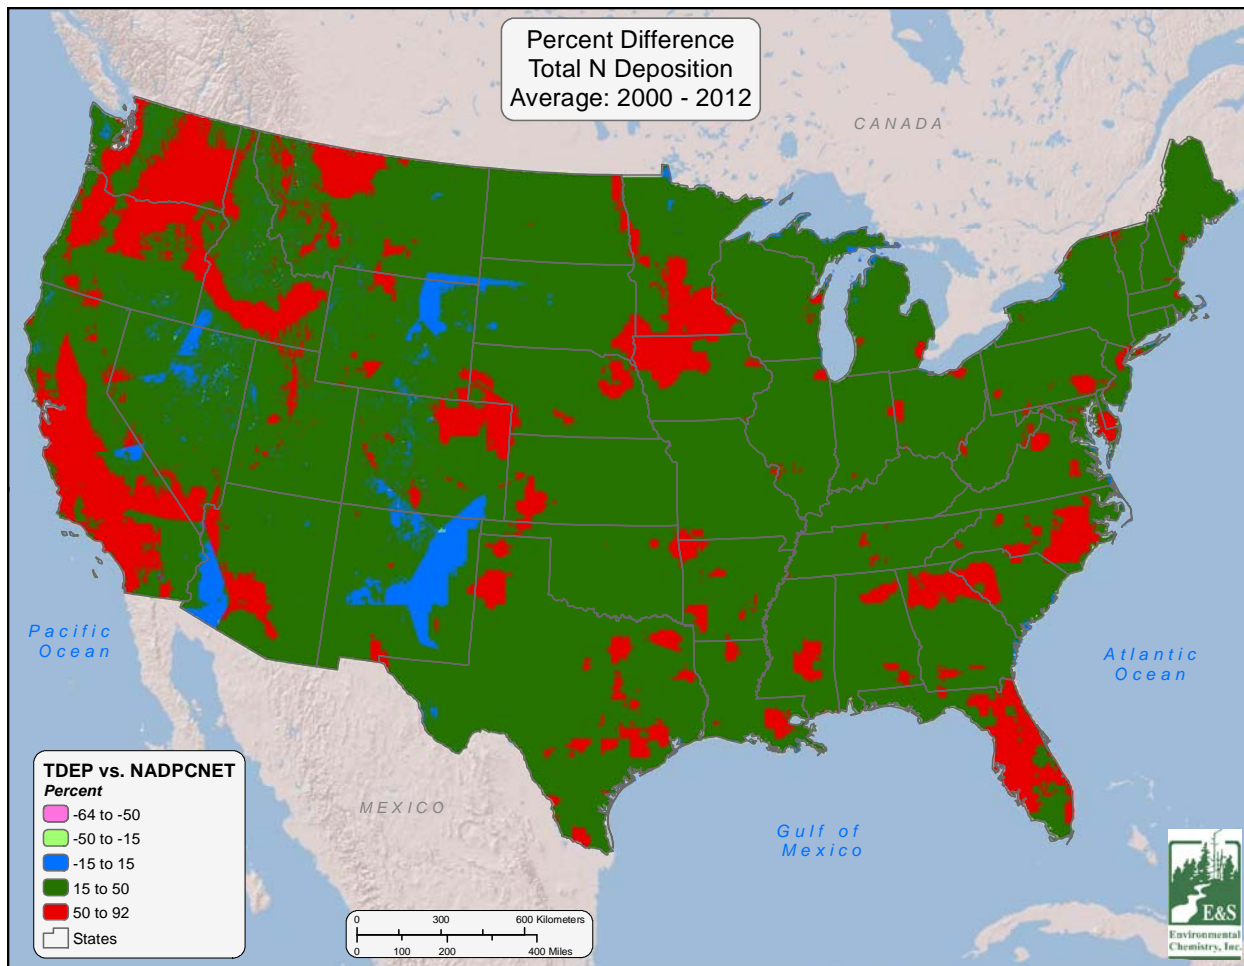

Figure 8. Percent difference between average annual (2000 – 2012) TDEP and NADP wet plus CASTNET dry total N deposition. A positive value indicates that the TDEP estimate is greater than NADP plus CASTNET.

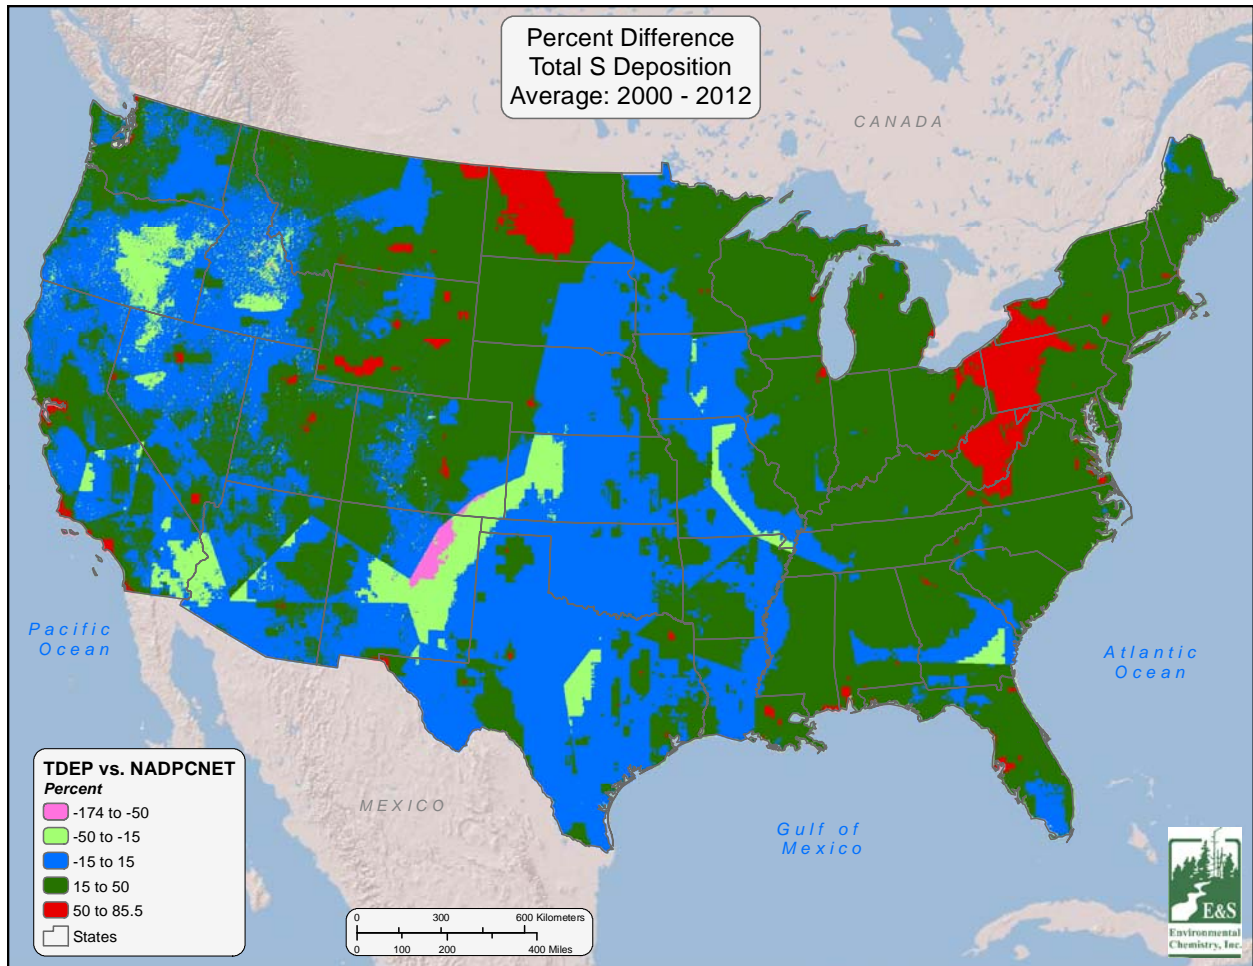

Figure 9. Percent difference between average annual (2000 – 2012) TDEP and NADP wet plus CASTNET dry total S deposition.

generated from TDEP were at many locations substantially higher than NADP plus CASTNET estimates. Such differences may affect conclusions drawn from analysis of these deposition data.

Comparison with CMAQ Model Estimates of Wet Plus Dry Deposition

Total N and S deposition generated from TDEP for comparison with results from CMAQ simulations are given in Figures 2 and 3. Results from the CMAQ simulations for total N deposition are given in Figure 10. There were many small scattered locations throughout the conterminous United States that received more than 15 kg N/ha/yr of total N deposition, based

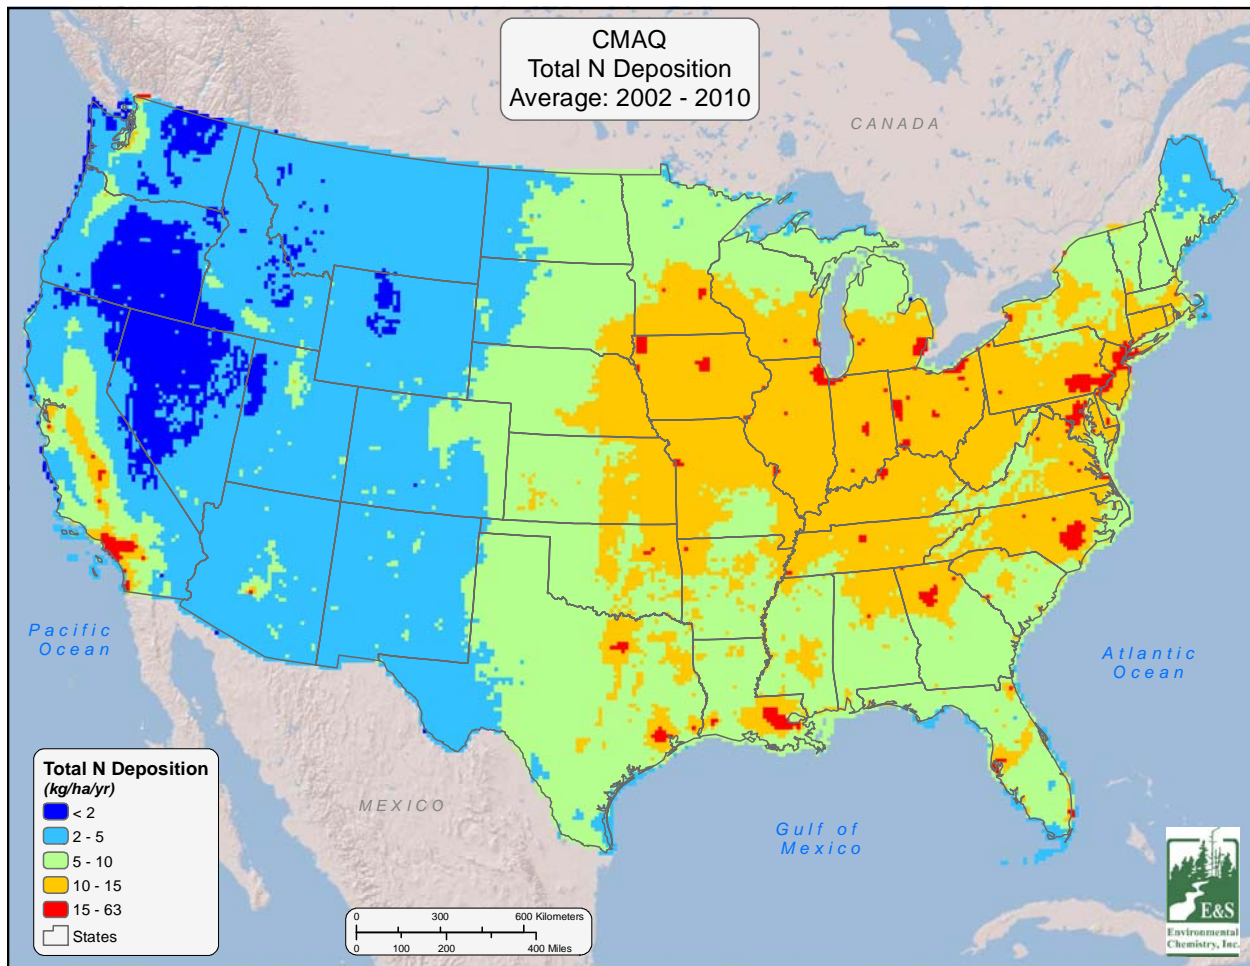

Figure 10. CMAQ average annual (2002 – 2010) total N deposition.

on CMAQ. Much of the eastern United States received simulated total N deposition higher than 10 kg N/ha/yr. Such high estimates of total N deposition were also found in parts of California. Virtually the entire eastern half of the conterminous United States (excluding the northern half of Maine) received estimated N deposition higher than 5 kg N/ha/yr.

CMAQ simulations of total S deposition were uniformly low (< 2 kg S/ha/yr) throughout most of the western United States, but mainly (with the exception of parts of Maine and Florida) above 5 kg S/ha/yr in the East (Figure 11). Highest simulated values of S deposition were centered around West Virginia, Pennsylvania, and Ohio.

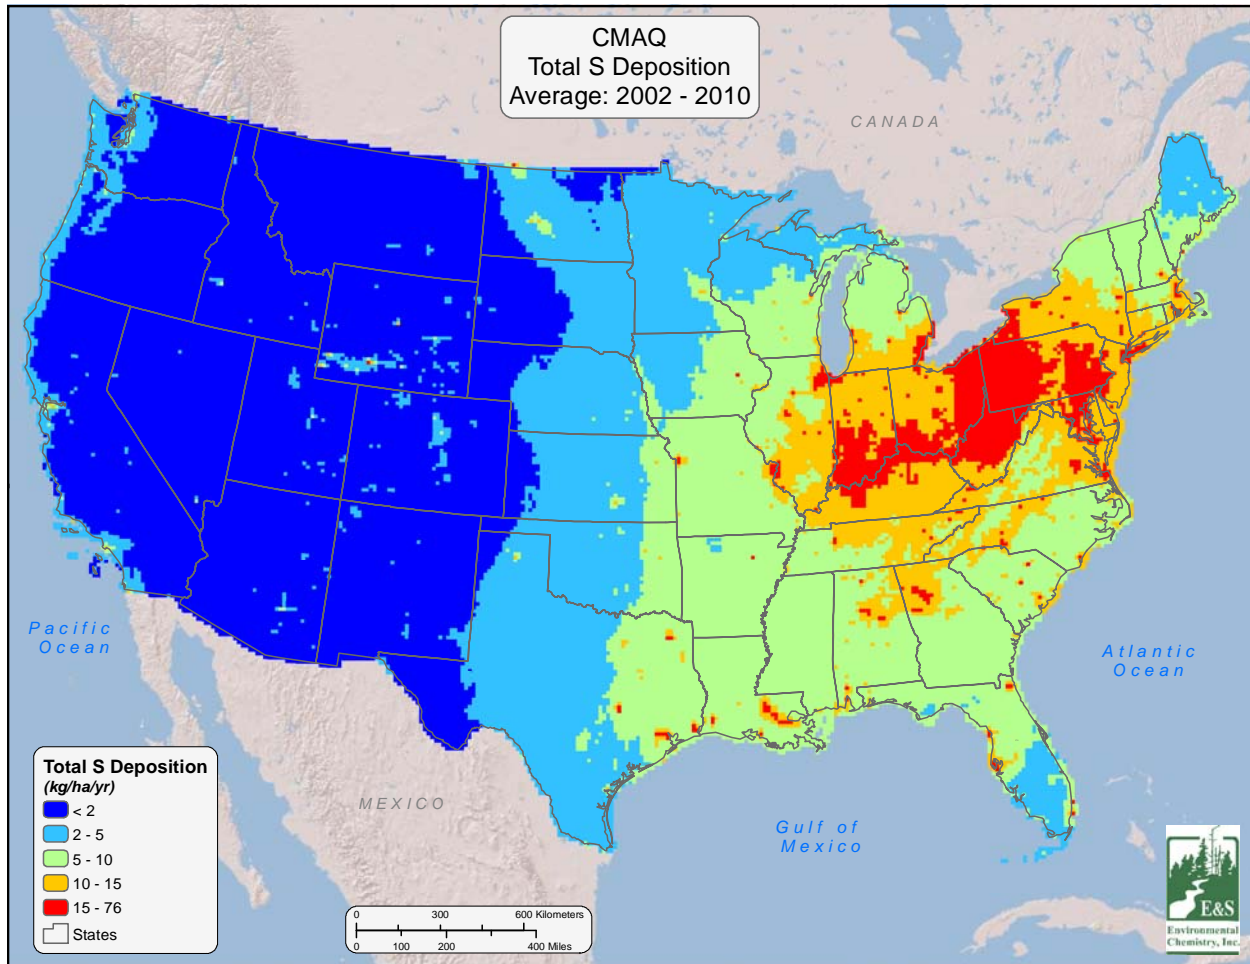

Figure 11. CMAQ average annual (2002 – 2010) total S deposition.

CMAQ simulations of total N deposition were higher than TDEP estimates at some locations and lower at other locations (Figure 12). The absolute difference (higher or lower) between TDEP and CMAQ estimates of total N deposition was generally less than 4 kg N/ha/yr.

Total S simulations with CMAQ were mainly within 4 kg S/ha/yr of TDEP estimates (Figure 13). The largest differences were in and around Pennsylvania and Ohio. Percent differences for N deposition exceeded 15% in many areas, and exceeded 50% at a few locations (Figure 14). Percent differences for S deposition were more pronounced, exceeding 50% at many locations (Figure 15).

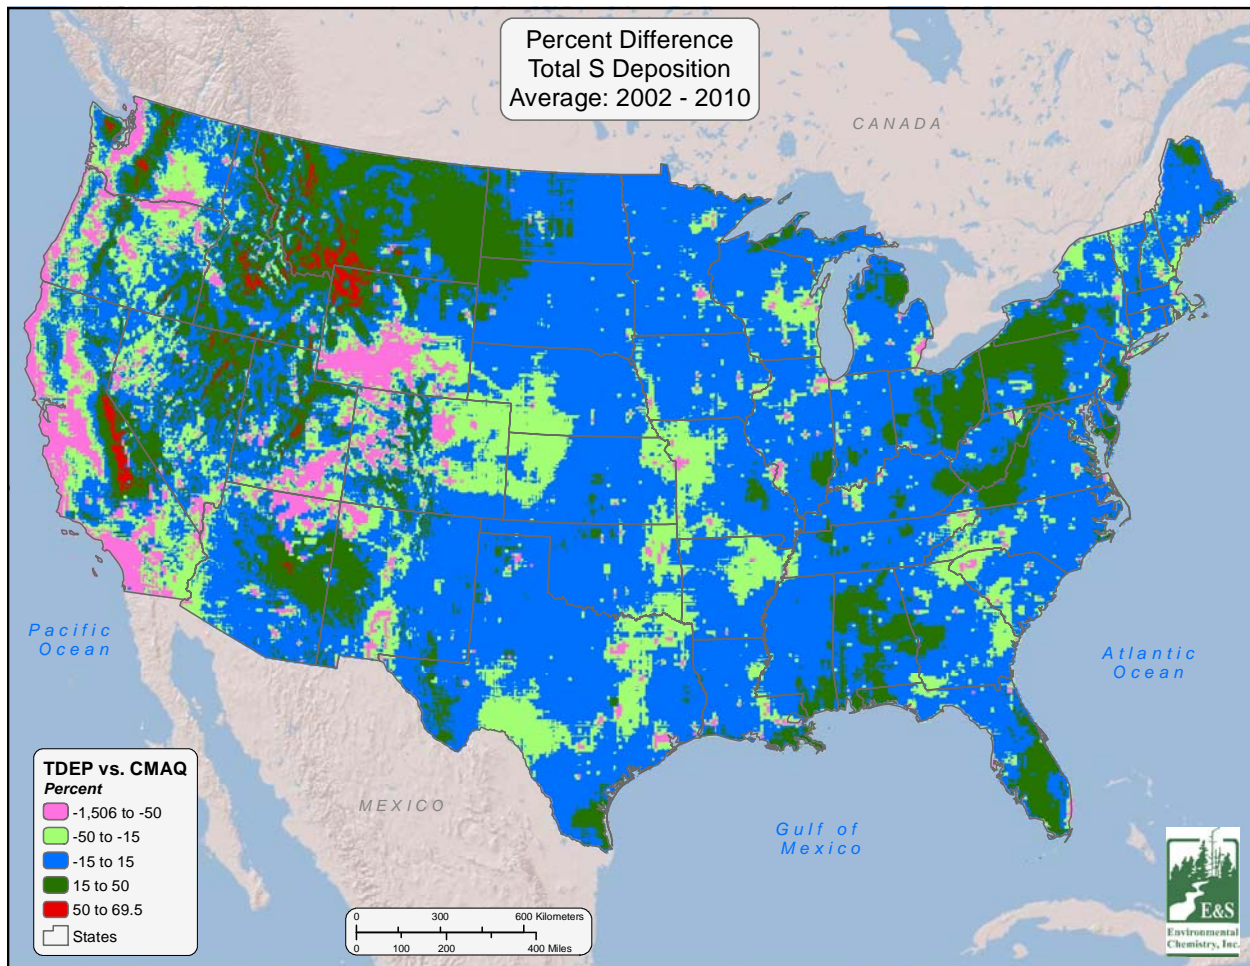

Figure 15. Percent difference between average annual (2002 – 2010) TDEP and CMAQ total S deposition.

Comparison with Grimm Interpolations of NADP Wet Deposition Plus CMAQ Simulations of Dry Deposition

The TDEP estimates to which the Grimm/CMAQ estimates are compared are shown in Figures 2 and 3. These comparisons are made only for the eastern United States, as this is the region for which Grimm interpolations have been developed. Grimm wet plus CMAQ dry estimates of total N deposition (Figure 16) show values between 5 and 10 kg N/ha/yr, mainly in the far north and the south, and above 10 kg N/ha/yr at other locations. Small scattered areas had estimated total N deposition higher than 15 kg N/ha/yr. Most of the eastern United States showed

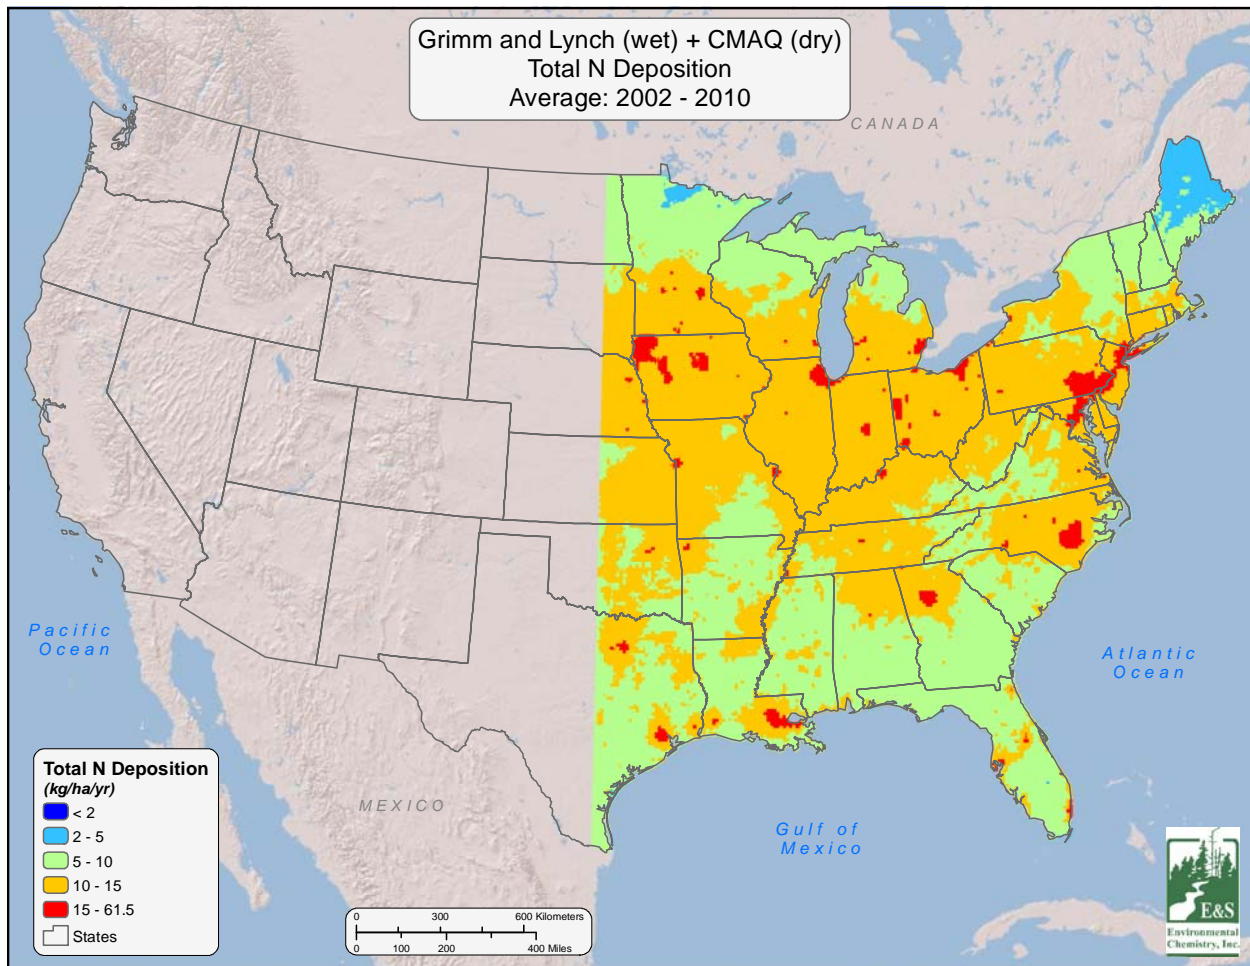

Figure 16. Grimm and Lynch (1997; GMLY) wet + CMAQ dry average annual (2002 – 2010) total N deposition.

estimated total S deposition above 5 kg S/ha/yr; exceptions included northern Maine and parts of southern Florida (Figure 17). Absolute differences were less than 4 kg N/ha/yr (Figure 18) and 4 kg S/ha/yr (Figure 19) at most locations. Larger differences were found at some locations, especially for S deposition.

Throughout much of the eastern United States, the two approaches yielded estimates of total N deposition that were within 15% of each other. Larger differences (15-50%) were also found at many locations, most commonly showing higher N deposition estimates for the Grimm wet plus CMAQ dry approach (Figure 20). Percent differences were mainly in the range of

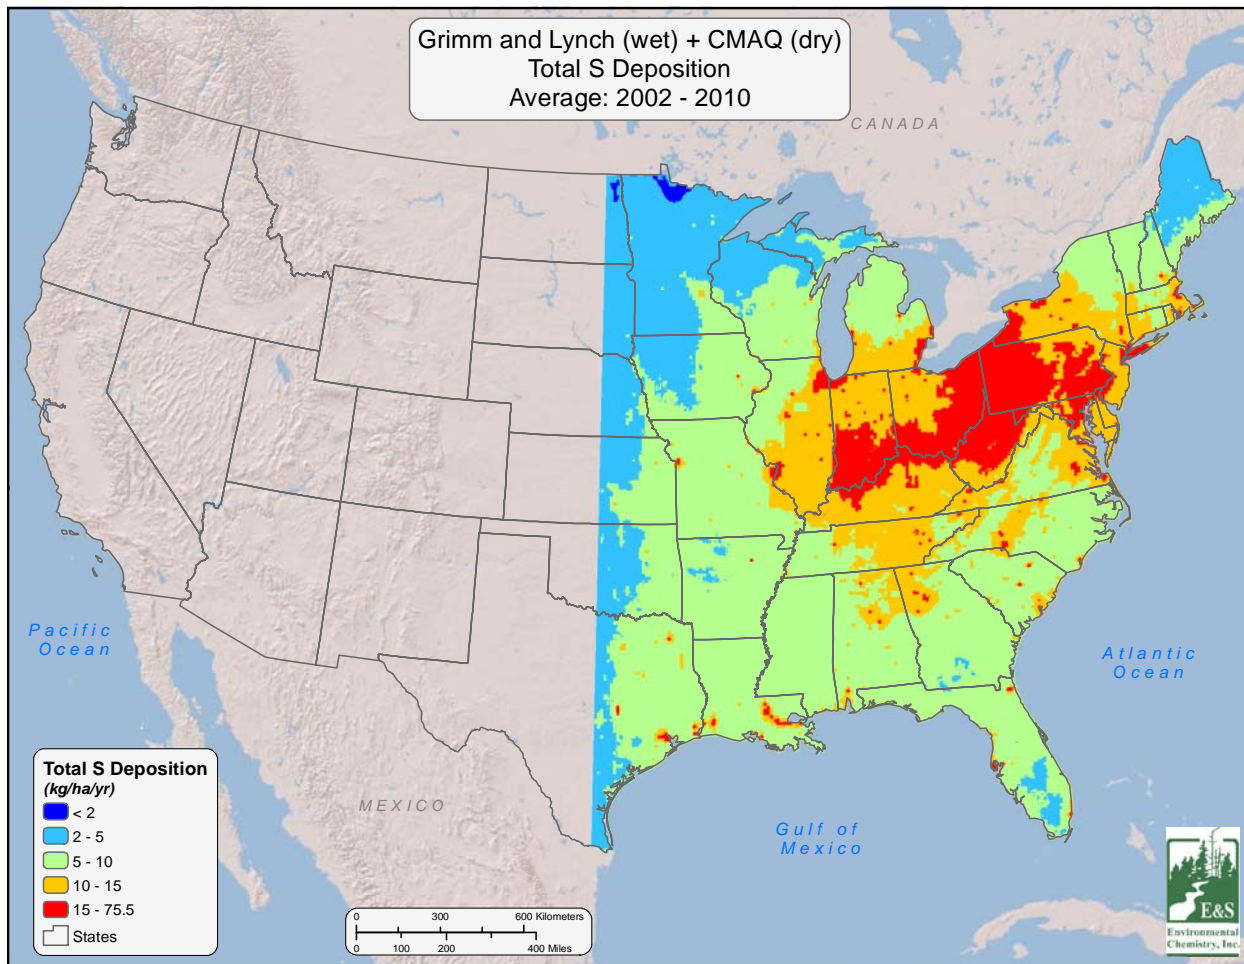

Figure 17. GMLY wet + CMAQ dry average annual (2002 – 2010) total S deposition.

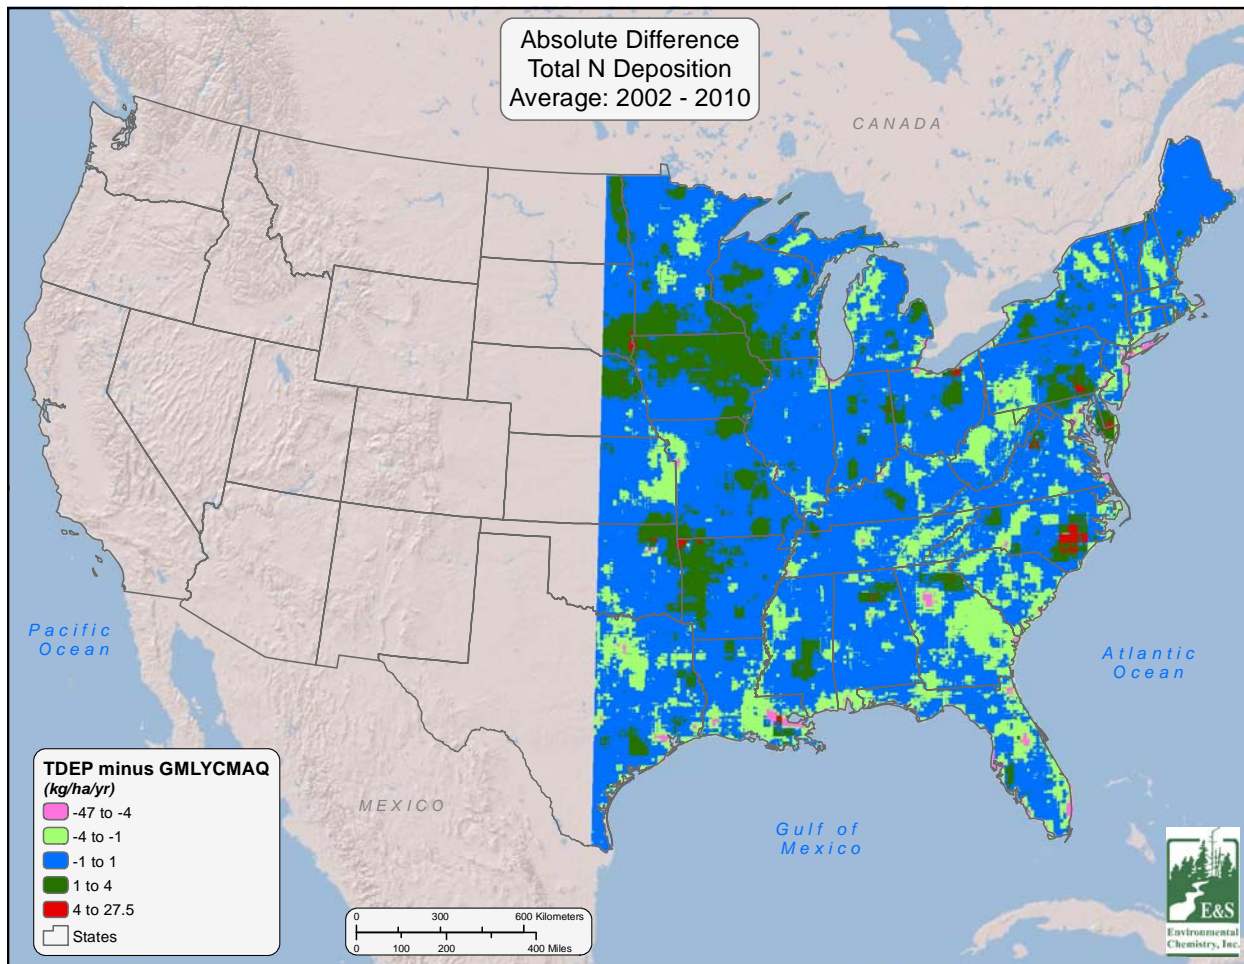

Figure 18. Absolute difference between average annual (2002 – 2010) TDEP and Grimm wet + CMAQ dry (GMLYCMAQ) total N deposition.

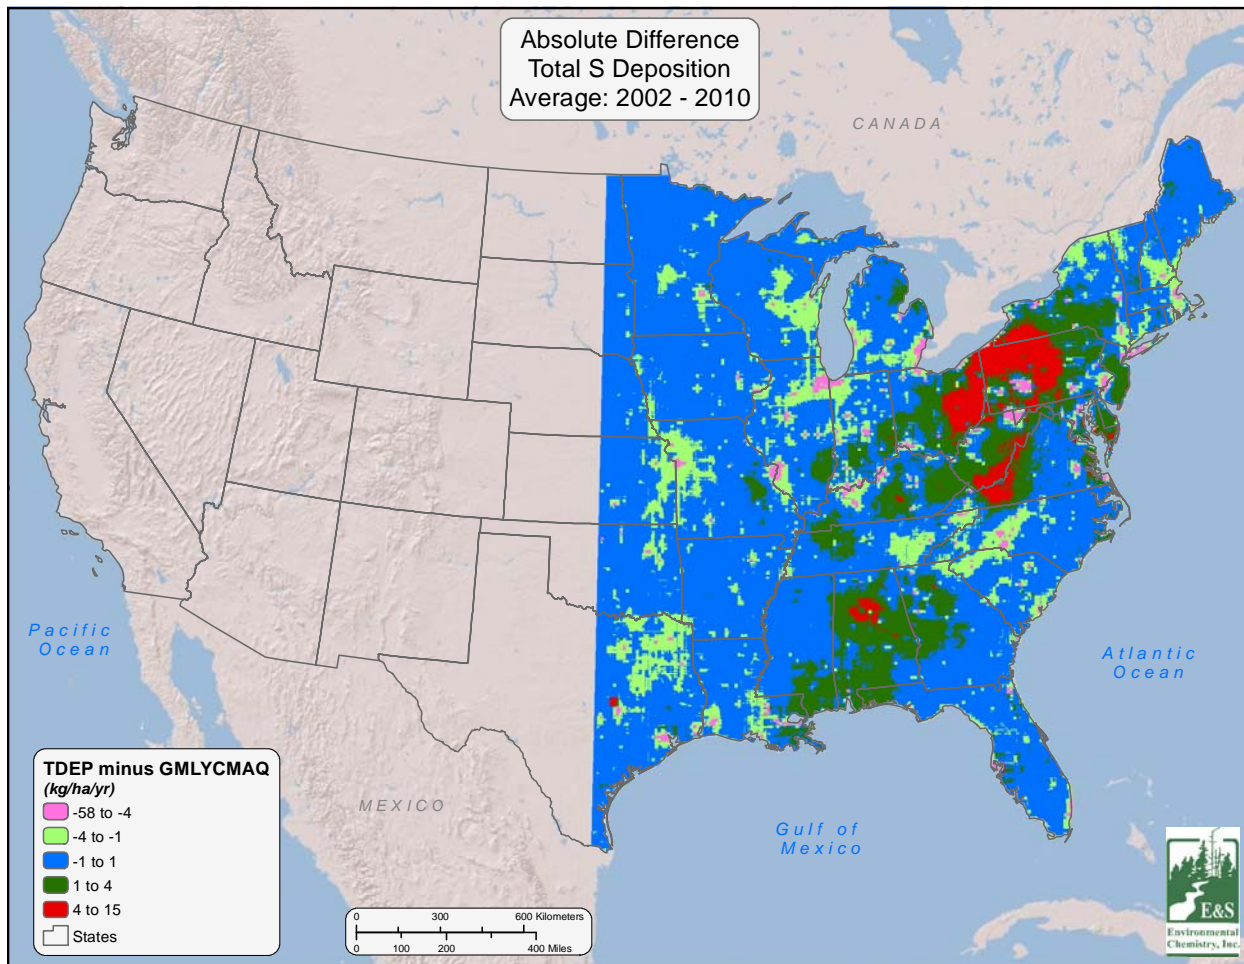

Figure 19. Absolute difference between average annual (2002 – 2010) TDEP and Grimm wet + CMAQ dry total S deposition.

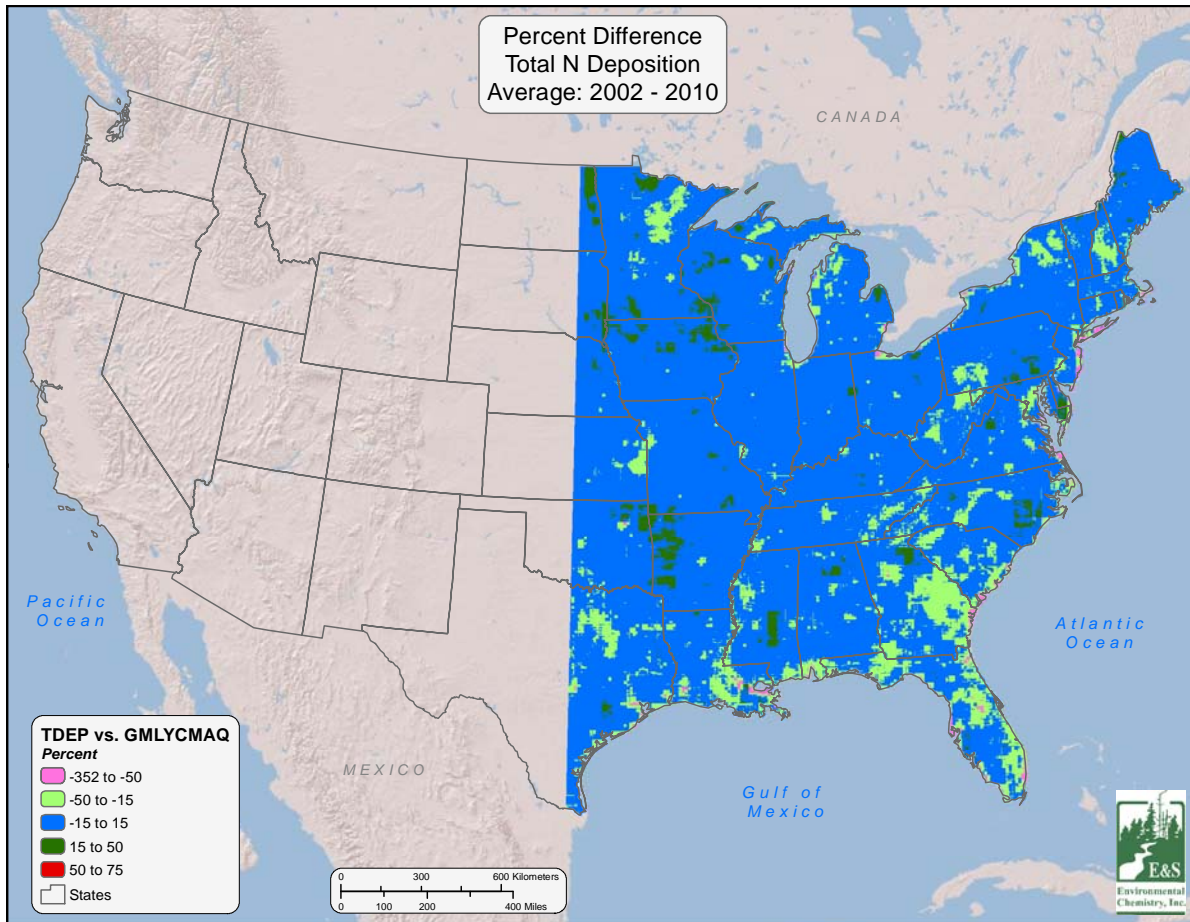

Figure 20. Percent difference between average annual (2002 – 2010) TDEP and Grimm wet + CMAQ dry total N deposition. A positive value indicates that the TDEP estimate is greater than Grimm wet + CMAQ dry.

±15%, with some areas showing larger percent differences. The larger percent differences generally indicated larger values for the Grimm and Lynch + CMAQ approach. The spatial extent of percent differences were more pronounced for estimates of S (Figure 21), and more areas showed TDEP having higher S deposition as compared with N deposition (Figure 20).

Comparison between TDEP (Wet Only) and Grimm (Wet Only) Estimates

Because a number of USFS studies have relied on Grimm interpolations of wet deposition (cf., Sullivan et al. 2004, Sullivan et al. 2008, Sullivan et al. 2011, Sullivan et al. 2012, McDonnell et al. 2013, McDonnell et al. In press), there is interest in examining the

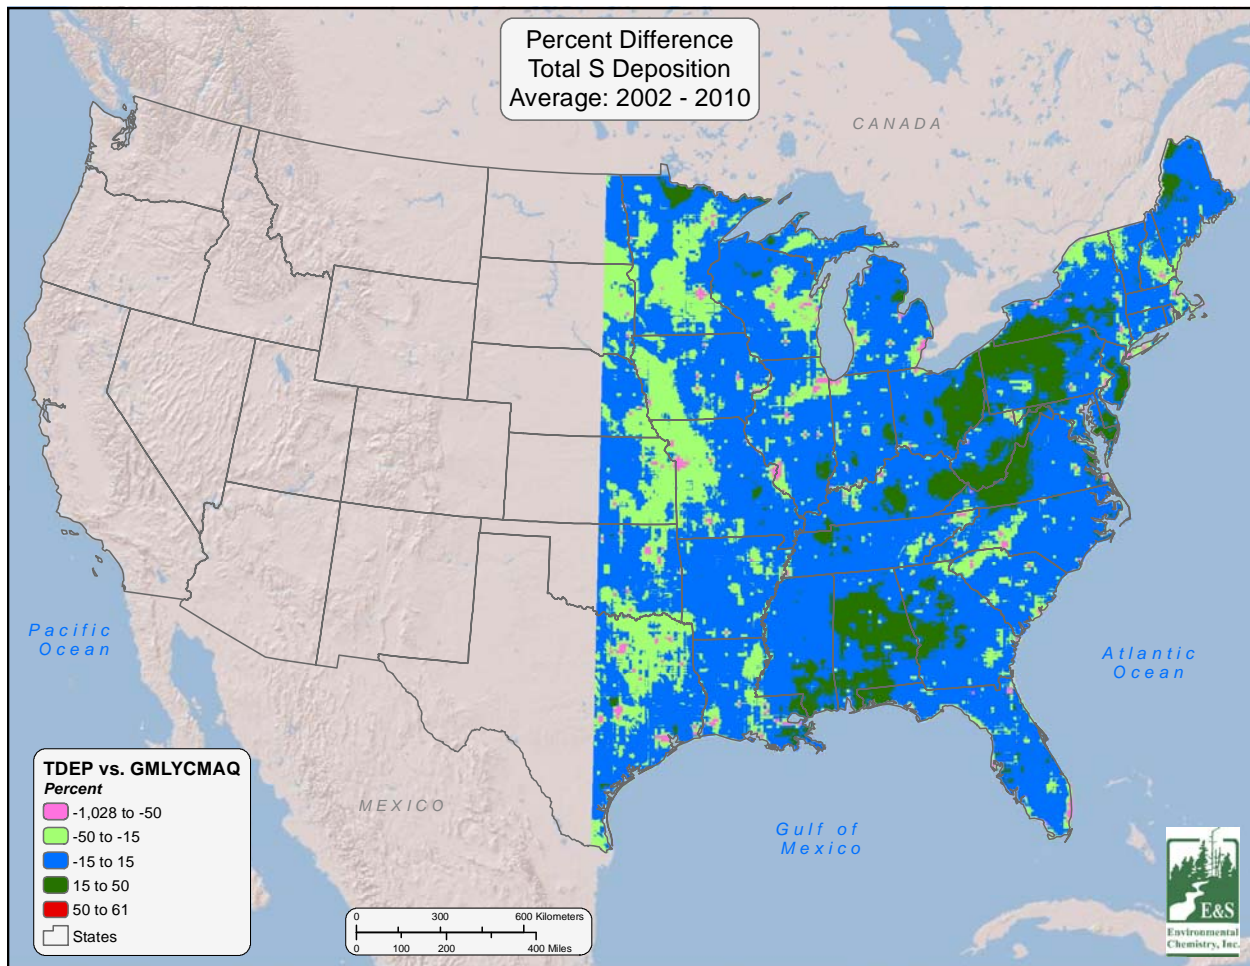

Figure 21. Percent difference between average annual (2002 – 2010) TDEP and Grimm wet + CMAQ dry total S deposition.

agreement between TDEP and Grimm estimates of wet only deposition of N and S. Results of these comparisons are depicted in Figures 22 through 29. Estimates of wet N from the TDEP simulations were less than 2 kg N/ha/yr throughout much of the western United States, and between 2 and 5 kg N/ha/yr elsewhere in the West and throughout much of the East (Figure 22). Highest wet N deposition estimates from the TDEP simulations (5-10 kg N/ha/yr) occurred across much of the Midwest and into the Northeast. In contrast, TDEP simulations of wet S deposition were consistently less than 2 kg S/ha/yr throughout the West and 2-5 kg S/ha/yr throughout most of the East. Higher TDEP simulations of wet S deposition occurred in a band

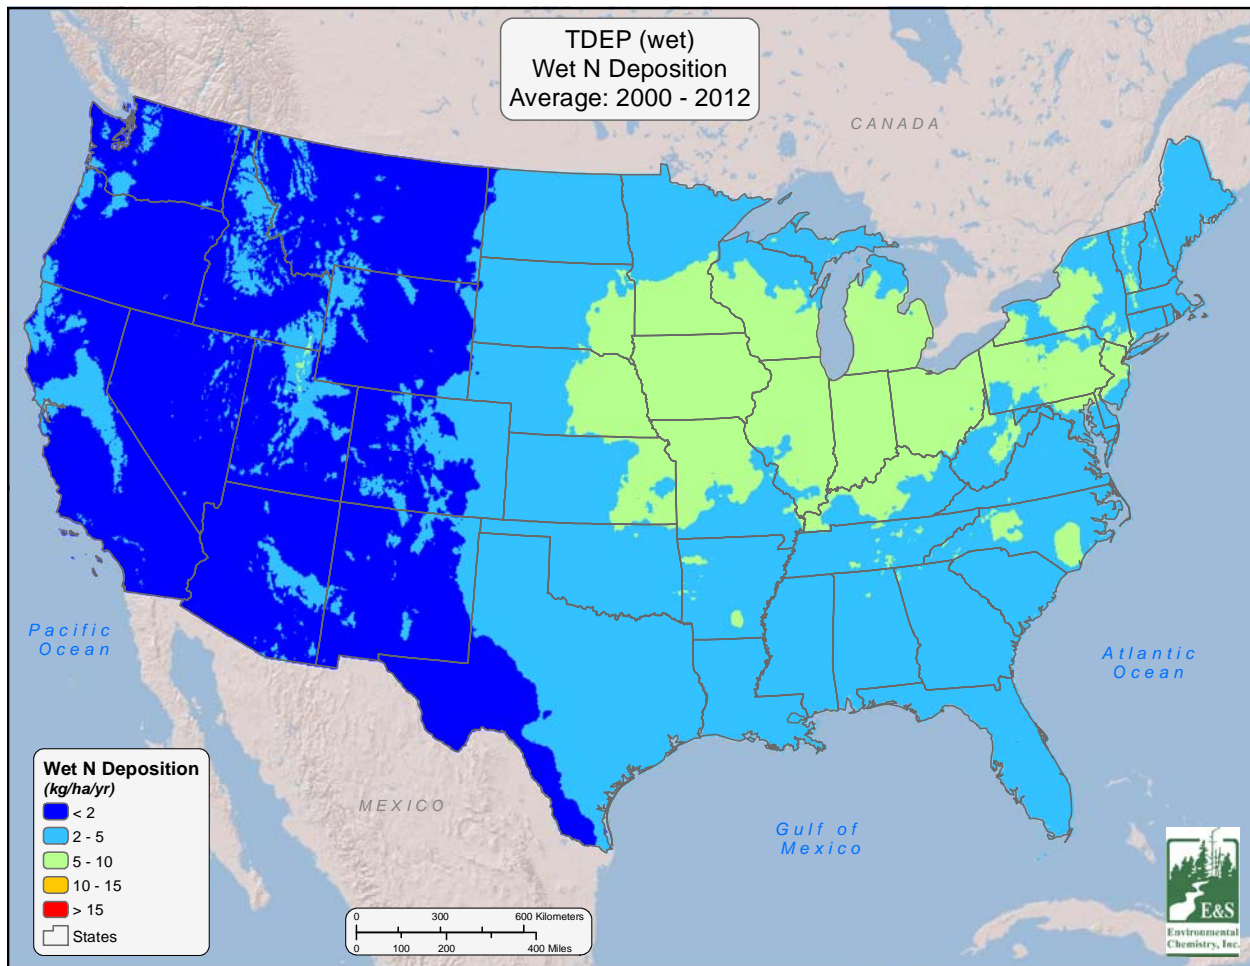

Figure 22. TDEP average annual (2000 – 2012) wet N deposition.

running from the Ohio Valley northeast to portions of New York (Figure 23). Grimm estimates of wet N deposition (Figure 24) and wet S deposition (Figure 25) were broadly similar to estimates of wet N deposition (Figure 22) and wet S deposition (Figure 23) generated by TDEP.

Thus, the absolute differences between TDEP and Grimm estimates of wet N (Figure 26) and wet S (Figure 27) deposition were similar at most locations (within 1 kg N or S/ha/yr). Percent differences were also similar (within 15% at most locations). Where percent differences exceeded 15%, TDEP values were most commonly lower, especially in the upper Midwest (Figures 28 and 29).

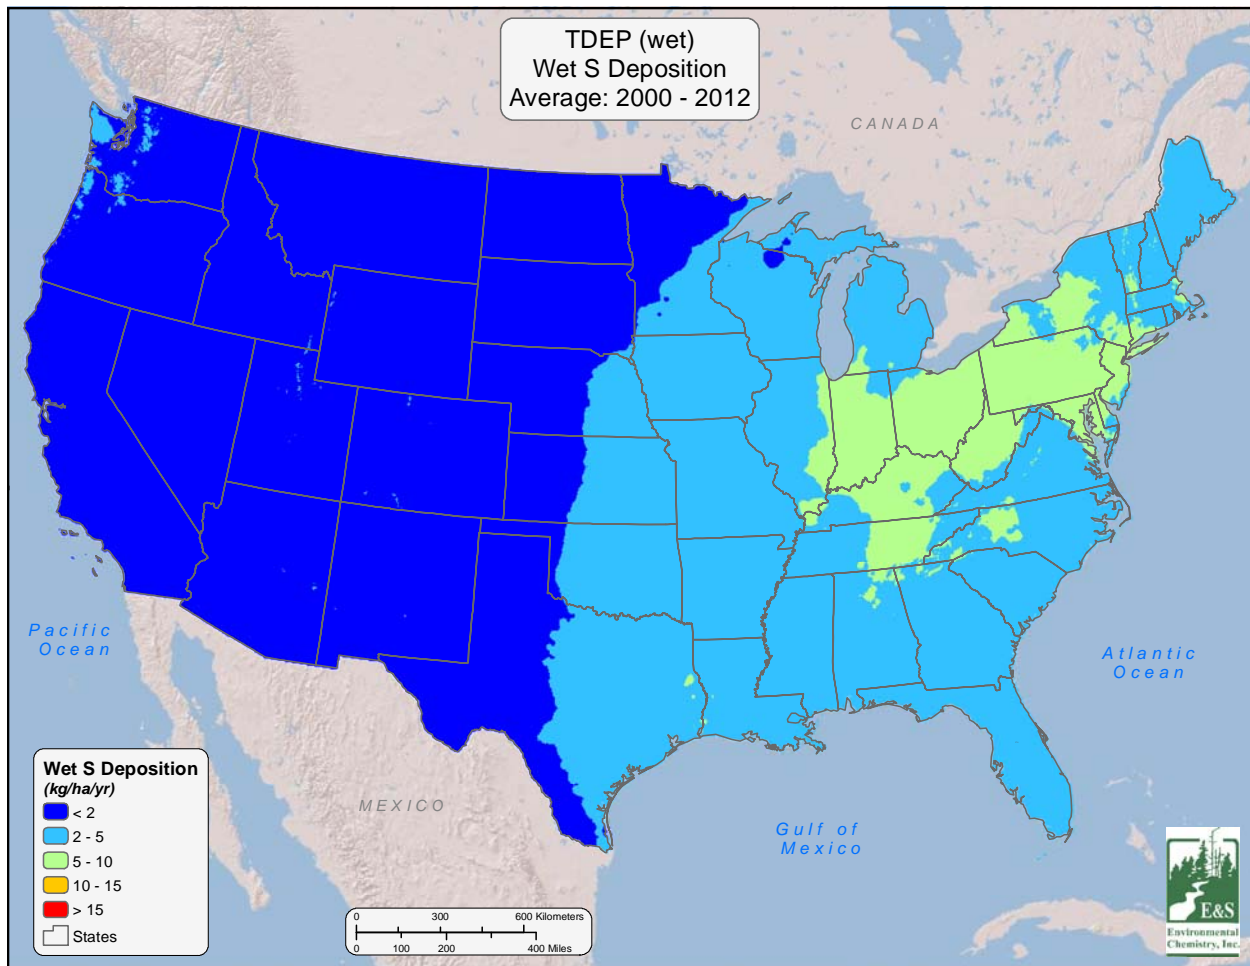

Figure 23. TDEP average annual (2000 – 2012) wet S deposition

Estimates for Individual National Forests and Wildernesses

Results obtained with the various methods used to estimate total and wet only N and S deposition for each of the individual national forests and wildernesses within the conterminous United States are summarized in Tables A-1 and A-2 in the Appendix. Results are presented as distributions of values found for a given deposition method, or comparison between two methods, across a given national forest or wilderness. Results provided in these tables are summarized as average values over the period 2000-2012. Results for any individual year or any

combination of years within the study period can be extracted from the database generated for this project.

For some national forests (Tables A-1 and A-2) and for some USFS wildernesses (Tables A-3 and A-4), differences in N and S deposition across methods were pronounced. Other comparisons yielded more similar results. For example, total N deposition estimates generated using TDEP for the Beaverhead National Forest are shown at the top of Table A-1 for two time periods (2000-2012 and 2002-2010). Results for the latter time period are given to facilitate direct comparison with the availability of CMAQ simulations at the time of the analyses for this report. For the full time period considered for this study (2000-2012), total N deposition estimates from TDEP within the Beaverhead NF ranged from as low as 1.8 kg N/ha/yr to as high as 6.5 kg N/ha/yr; the mean value was 3.1 kg N/ha/yr. In contrast, the mean N deposition within that forest was only 1.9 kg N/ha/yr based on NADP-wet plus CASTNET-dry N deposition. Results of estimates of N deposition at other NFs are also given in Table A-1. Results of estimated S deposition, by NF, are given in Table A-2. Analogous results for wildernesses are provided in Tables A-3 and A-4. Deposition estimates for individual years are provided in the project database.

Dry-to-Wet Ratios

Observed differences in deposition estimates at a given location and time period were driven mostly by differing estimates of dry deposition. In general, estimates of wet deposition were more similar across methods than were estimates of dry deposition. This pattern can be seen by mapping the dry-to-wet ratios for N and S deposition (Figures 30 and 31). The dry:wet ratio for N deposition was generally similar between TDEP (Figure 30a) and CMAQ (Figure 30b), both of which showed dry:wet N deposition > 1.15 throughout much of the conterminous

United States. In contrast, dry:wet deposition values generated from NADP-wet plus CASTNET-dry estimates were < 0.85 throughout nearly the entire conterminous United States except southern California and other parts of the desert Southwest (Figure 30c). At many locations, the ratio was less than 0.5 (wet more than double dry).

The dry-to-wet ratios of S deposition were broadly similar between TDEP (Figure 31a) and CMAQ (Figure 31b). Dry S deposition estimates were mostly higher than 1.15 in the Northeast, Southwest, and Upper Midwest and lower elsewhere. Dry-to-wet ratios of S deposition generated using NADP + CASTNET data were almost uniformly < 0.85 except in the desert Southwest (Figure 31b).

Relationships with Precipitation

As demonstrated in the previous sections of this report, there were, at many locations, substantial differences in estimated N and S deposition among methods. Determination of the reasons for those differences is beyond the scope of this study. We did, however, conduct a preliminary analysis to determine whether intermethod differences showed any relationship with annual precipitation and/or elevation, two landscape variables that might be expected to influence deposition levels. Such relationships, if they exist, might vary by region. We focused this cursory analysis on FS Region 8 in the southeastern United States. For this analysis, we calculated the average values of deposition and annual precipitation or elevation in each wilderness. Precipitation data were obtained from long-term (1981-2010) averages from PRISM at 800-m resolution (<http://www.prism.oregonstate.edu/normals/>). Elevation data were obtained from the USGS national elevation dataset at 200 m resolution (<http://ned.usgs.gov/>). These data were used to derive average precipitation and elevation for each wilderness included in this study.

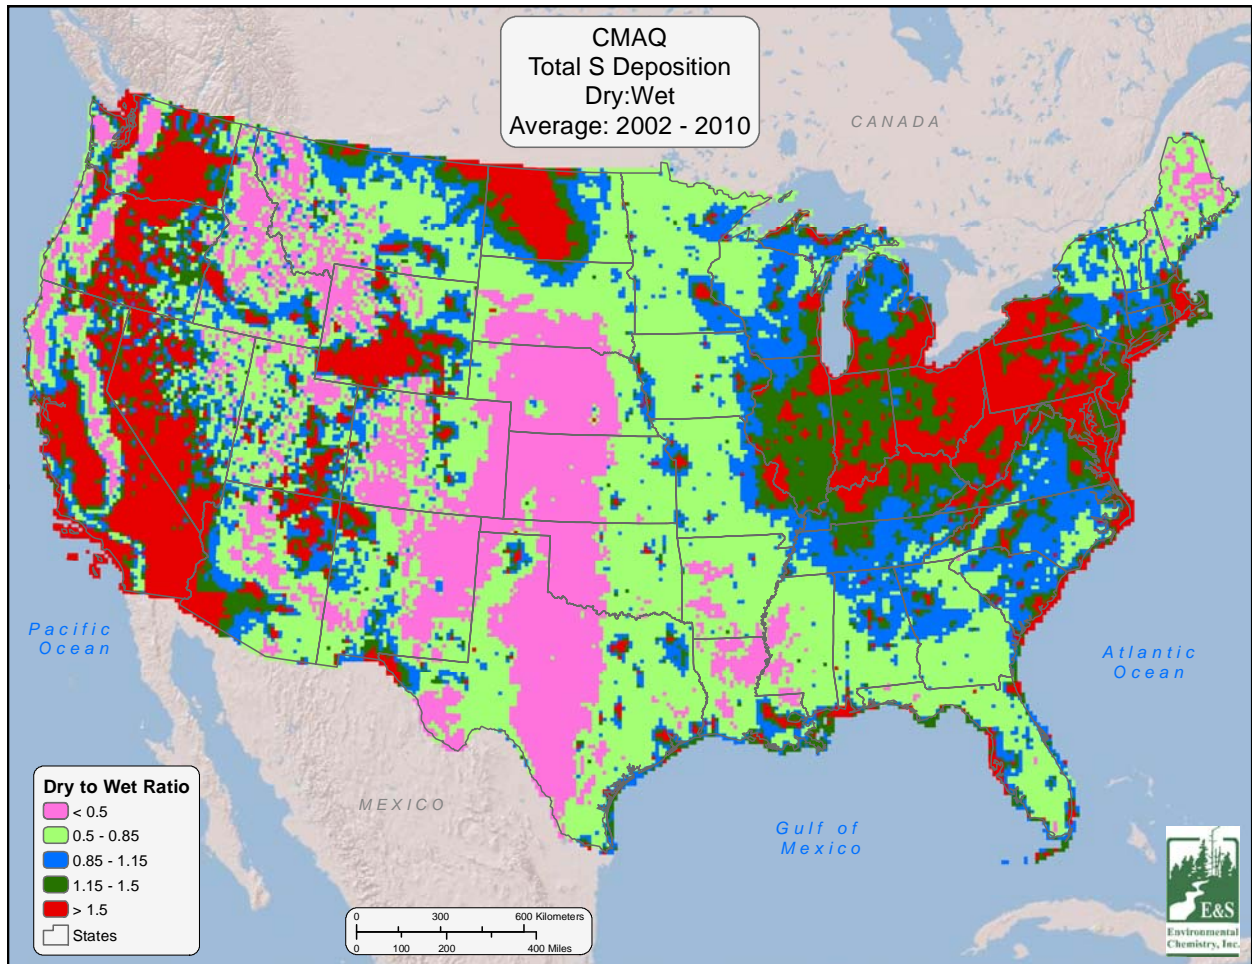

Figure 31. Continued.

In general, differences in deposition of N or S between TDEP and the other total (wet plus dry) deposition estimation methods were largest in wildernesses in Region 8 that experienced relatively low precipitation (Figure 32). These patterns with precipitation held for both N (Figure 32a) and S (Figure 32b) deposition. Differences between the two wet deposition estimates (TDEP-wet minus GMLY wet) did not show clear patterns with precipitation. Analogous patterns with elevation were not evident.
